The selector stops at the node when the two alternatives tie. The formal evaluator returns the cut, its cost, and three operation counters together.

Source: KomorebiPaperV/PruningAlgorithm.lean.

```
noncomputable def solve (c : A → ℝ) : (t : FiniteAdaptive.Tree A) → Result t
  | .leaf a => ⟨.stop _, c a, 0, 0, 1⟩
  | .branch a n ch =>
      let child := fun i => solve c (ch i)
      let total := ∑ i, (child i).cost
      let stop := c a ≤ total
      ⟨if stop then .stop _ else .split (fun i => (child i).cut),
       min (c a) total,
       1 + ∑ i, (child i).comparisons,
       (n+1) + ∑ i, (child i).additions,
       1 + ∑ i, (child i).visits⟩
```

The child results are introduced once as a family, and their stored costs are summed. The correctness theorem identifies both outputs with the specification: cost equals `value`, and cut equals `best`.

Source: KomorebiPaperV/PruningAlgorithm.lean.

```
theorem solve_correct (c : A → ℝ) (t : FiniteAdaptive.Tree A) :
    (solve c t).cost = value c t ∧ (solve c t).cut = best c t := by
  induction t with
  | leaf a => exact ⟨rfl,rfl⟩
  | branch a n ch ih =>
    have hc : (∑ i, (solve c (ch i)).cost) = ∑ i, value c (ch i) :=
      Finset.sum_congr rfl (fun i _ => (ih i).1)
    constructor
    · simp only [solve, value, hc]
    · simp only [solve, best, hc]
      split_ifs
      · rfl
      · congr 1
        funext i
        exact (ih i).2
```

The proof uses tree induction. In a branch, the induction hypotheses identify all cached child values with their specification values. The same comparison then controls both the evaluator and the specification, including equality.

6.8 An explicit small tree

Consider a root r with two leaf children a and b. Its complete prunings are $\{r\}$ and $\{a, b\}$. Set $c(r) = 7$, $c(a) = 2$, and $c(b) = 3$. The split costs 5 and is selected. The gap to the other pruning is 2.

Changing $c(r)$ to 5 creates a tie. The selector now stops at the root by convention. This deterministic choice is defined, but it is not protected by a positive separation margin. An arbitrarily small perturbation can change which pruning has smaller cost. Tie handling and strict stability address different questions.

If $p(r) = p(a) + p(b) = I$, both prunings synthesize exactly. At a tie, two representations can exchange preference while both preserve the full signal through the same synthesis identity.

6.9 What the linear-work count charges

The source proves one visit per node, one comparison per internal node, and one addition per edge. The last identity is expressed as additions plus one equals the node count. Combining them yields

Source: KomorebiPaperV/PruningAlgorithm.lean.

```
theorem solve_linear_work (c : A → ℝ) (t : FiniteAdaptive.Tree A) :
    (solve c t).visits + (solve c t).comparisons + (solve c t).additions ≤ 3 * nodes t := by
  have hv := solve_visits c t
  have hc := solve_comparisons c t
  have ha := solve_additions c t
  have hi := internal_le_nodes t
  omega
```

Node costs are supplied inputs. Their estimation from data, the cost of exact real arithmetic, output serialization, and the runtime behavior of a particular compiler are not charged by this theorem. The claimed bound is precise for its stated unit operation model. It is not a wall clock performance certificate or a cost bound for a nonadditive objective.

6.10 The exact worst pruning error envelope

Suppose local perturbations obey $|d(v) - c(v)| \le e(v)$. The maximum possible sum of the error weights along a complete pruning has the recurrence

$$E(v) = \max\left(e(v), \sum_{u \text{ child of } v} E(u)\right).$$

Source: KomorebiPaperV/FiniteAdaptive.lean.

```
noncomputable def envelope (e : A → ℝ) : Tree A → ℝ
  | .leaf a => e a
  | .branch a _ children => max (e a) (∑ i, envelope e (children i))
```

The source proves both that every cut weight is at most this envelope and that some cut attains it. It is therefore the exact maximum of the additive weights over complete prunings, rather than a loose sum over all nodes.

For the two-leaf example, if $e(r) = 0.3$ and $e(a) = e(b) = 0.2$, then $E(r) = \max(0.3, 0.4) = 0.4$. Both candidate objective values are perturbed by at most 0.4. The original gap is 2, and $2E(r) = 0.8 < 2$, so the selected split is protected.

6.11 Why the margin contains a factor of two

When comparing a competitor with the minimizer, the competitor can move down by the full error budget while the minimizer moves up by the same budget. Their separation can shrink by twice the budget. The antichain theorem preserves the selected pruning under the strict inequality.

Source: `KomorebiPaperV/PruningSums.lean`.

```
theorem antichain_selector_stable (c d e : A → ℝ) (h : ∀ a, |d a-c a| ≤ e a)
    (t : FiniteAdaptive.Tree A) (γ : ℝ)
    (hg : ∀ S : Pruning t, S ≠ selected c t → γ ≤ nodeSum c S-nodeSum c (selected c t))
    (hm : 2*envelope e t < γ) : selected d t = selected c t := by
  apply congrArg (pruningEquiv t)
  apply best_unchanged_of_gap c d e h t γ _ hm
  intro q hq
  have hne : pruningEquiv t q ≠ selected c t := fun he => hq ((pruningEquiv t).injective he)
  simpa only [selected, pruning_nodeSum] using hg (pruningEquiv t q) hne
```

Equality at the boundary is insufficient in general. With an original gap $\gamma = 2$ and budget $E = 1$, the winner can move up by one and the competitor down by one, producing a tie. A deterministic tie rule can then change the selected object. The theorem's strict inequality is part of its content.

6.12 Probability is transferred from a joint event

The probabilistic statement assumes one event on which all required local inequalities hold simultaneously. Deterministic stability then makes that event a subset of the event that the selector is unchanged.

Source: `KomorebiPaperV/PruningAlgorithm.lean`.

```
theorem antichain_probability {Ω : Type*} [MeasurableSpace Ω]
    (μ : MeasureTheory.Measure Ω) (good : Set Ω) (δ : ENNReal)
    (c e : A → ℝ) (d : Ω → A → ℝ) (t : FiniteAdaptive.Tree A) (γ : ℝ)
    (hgood : ∀ ω ∈ good, ∀ a, |d ω a-c a| ≤ e a)
    (hg : ∀ S : Pruning t, S ≠ selected c t → γ ≤ nodeSum c S-nodeSum c (selected c t))
    (hm : 2*envelope e t < γ) (hprob : 1-δ ≤ μ good) :
    1-δ ≤ μ {ω | selected (d ω) t = selected c t} := by
  apply hprob.trans
  apply MeasureTheory.measure_mono
  intro ω hω
  exact antichain_selector_stable c (d ω) e (hgood ω hω) t γ hg hm
```

Separate marginal statements for each node do not automatically give the same probability for their intersection. One needs a supplied joint event or an additional argument, such as a correctly budgeted union bound. No independence assumption or tail concentration theorem is inferred by the source.

The theorem is written for a measure with an explicit lower bound `1-δ ≤ μ good`. Lean's measure notation also evaluates arbitrary sets through the associated outer measure, so the set-inclusion proof

does not itself establish event measurability. For ordinary success probabilities, use a probability measure, measurable random node costs, and a measurable joint good event. The selector on a finite tree is then determined by finitely many measurable comparisons, making its success event measurable. Finite tree structure alone cannot make arbitrary random cost functions measurable. The mathematical text makes these probability hypotheses explicit. In Part II, consistency statements based only on probabilities tending to one are interpreted as convergence in probability. Almost-sure conclusions need additional hypotheses and an argument such as summable failure probabilities.

7 Formal cyclic products and projective Smith actions

7.1 A formal residue projector filters coefficients

For a formal power series $f = \sum_{n \geq 0} f_n X^n$, the jth cyclic projector retains the degrees congruent to j modulo N.

Source: KomorebiPaperV/CyclicSeries.lean.

```
def cyclicProjector (N j : ℕ) (f : R⟦X⟧) : R⟦X⟧ :=
  PowerSeries.mk fun n => if n % N = j % N then PowerSeries.coeff n f else 0
```

The ambient coefficient ring is a commutative semiring. There is no evaluation point and no convergence assumption in this definition. Multiplication is the formal Cauchy product, whose individual coefficients are finite sums.

The projector laws express idempotence, disjointness of different residue classes, and resolution of the identity for $N > 0$. A pure packet in residue i multiplied by one in residue j lies in residue $i + j$ modulo N.

7.2 The complete cyclic product law

Decompose both factors into packets, distribute multiplication, and retain only pairs whose residue labels add to the requested output label.

Source: KomorebiPaperV/CyclicSeries.lean.

```
theorem cyclic_product_law {N : ℕ} (hN : 0 < N) (k : ℕ) (f g : R⟦X⟧) :
    cyclicProjector N k (f * g) =
      ∑ i ∈ Finset.range N, ∑ j ∈ Finset.range N,
        if (i + j) % N = k % N then
          cyclicProjector N i f * cyclicProjector N j g
        else 0 := by
  calc
    cyclicProjector N k (f * g) =
        cyclicProjector N k
          ((∑ i ∈ Finset.range N, cyclicProjector N i f) *
            (∑ j ∈ Finset.range N, cyclicProjector N j g)) := by
      rw [sum_cyclicProjector hN, sum_cyclicProjector hN]
    _ = ∑ i ∈ Finset.range N, ∑ j ∈ Finset.range N,
          if (i + j) % N = k % N then
            cyclicProjector N i f * cyclicProjector N j g
```

```
          else 0 := by
      rw [Finset.sum_mul]
      simp_rw [Finset.mul_sum]
      rw [cyclicProjector_sum]
      apply Finset.sum_congr rfl
      intro i hi
      rw [cyclicProjector_sum]
      apply Finset.sum_congr rfl
      intro j hj
      by_cases hlabel : (i + j) % N = k % N
      · simp only [hlabel, ↓reduceIte]
        rw [cyclicProjector_eq_of_mod_eq (i := k) (j := (i + j) % N)
          (by simpa using hlabel.symm)]
        exact cyclicProjector_product_packet N i j f g
      · simp only [hlabel, ↓reduceIte]
        exact cyclicProjector_product_other (R := R) (fun h => hlabel h.symm) f g
```

For $N = 2$, write $f = f_0 + f_1$ and $g = g_0 + g_1$. Then

$$(fg)_0 = f_0 g_0 + f_1 g_1, \qquad (fg)_1 = f_0 g_1 + f_1 g_0.$$

The subscripts label degree parity. They are not independent scalar coefficients. This formula explains nonlinear coupling between packet labels without leaving the formal-series setting.

7.3 Powers include the empty product

The power theorem sums over all q-tuples of residue labels, retaining those whose sum has the requested residue.

Source: KomorebiPaperV/CyclicSeries.lean.

```
theorem cyclic_power_law {N : ℕ} (hN : 0 < N) (k q : ℕ) (f : R⟦X⟧) :
    cyclicProjector N k (f ^ q) =
      ∑ i : Fin q → Fin N, if (∑ a, (i a).val) % N = k % N then
        ∏ a, cyclicProjector N (i a).val f else 0 := by
  classical
  have hex : f ^ q = ∑ i : Fin q → Fin N, ∏ a, cyclicProjector N (i a).val f := by
    have h := Fintype.sum_pow (fun i : Fin N => cyclicProjector N i.val f) q
    rw [sum_fin_projector hN] at h
    exact h
  rw [hex, cyclicProjector_sum]
  apply Finset.sum_congr rfl
  intro i _
  exact project_finite_product N k Finset.univ (fun a => (i a).val)
    (fun a => cyclicProjector N (i a).val f)
    (fun a _ => cyclicProjector_idempotent N (i a).val f)
```

At $q = 0$, the type `Fin 0 → Fin N` has one function, the empty assignment. Its sum of labels is zero and its product is one. Thus the formula returns the constant series one for the zero residue and zero otherwise. This boundary case is part of the statement, not an unstated convention added afterward.

The foundational coefficient-projector proofs identify their adaptation from Chapter IV in source comments and in the cumulative census. Reusing them in a new application does not make them independent additional discoveries. Analytic root-of-unity formulas require their own convergence domain when formal series are evaluated.

7.4 Use homogeneous coordinates at poles

For a nonzero complex parameter a, the normalized homogeneous Smith action is

$$A_a \begin{pmatrix} u \\ v \end{pmatrix} = \frac{1}{2} \begin{pmatrix} 1+a & 1-a \\ 1-a & 1+a \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix}.$$

Source: `KomorebiPaperV/SmithAction.lean`.

```
noncomputable def action (a : ℂ) (p : ℂ × ℂ) : ℂ × ℂ :=
  (((1 + a) * p.1 + (1 - a) * p.2) / 2,
   ((1 - a) * p.1 + (1 + a) * p.2) / 2)
```

The source proves $A_a A_b = A_{ab}$, $A_1 = I$, and preservation of nonzero pairs when $a \neq 0$. Multiplying both input coordinates by the same nonzero scalar multiplies both output coordinates by that scalar.

A projective point is a nonzero pair modulo this common scaling. The source constructs the equivalence relation explicitly.

Source: `KomorebiPaperV/SmithCyclic.lean`.

```
noncomputable def pointSetoid : Setoid Point where
  r := same
  iseqv := {
    refl := by intro p; exact ⟨1, one_ne_zero, by simp⟩
    symm := by
      rintro p q ⟨c, hc, hq⟩
      refine ⟨c⁻¹, inv_ne_zero hc, ?_⟩
      rw [hq]
      simp [hc]
    trans := by
      rintro p q r ⟨c, hc, hq⟩ ⟨d, hd, hr⟩
      exact ⟨d*c, mul_ne_zero hd hc, by rw [hr, hq]; simp [mul_assoc]⟩ }
```

The quotient is the full projective line in this coordinate model. It includes $[0 : 1]$, representing zero impedance, and $[1 : 0]$, representing infinity. The action respects scaling, so it descends to the quotient.

7.5 Cyclic composition

The parameter $\omega_N = \exp(2\pi i/N)$ is nonzero and satisfies $\omega_N^N = 1$ for $N > 0$. The resulting projective actions compose by addition of exponents modulo N.

Source: KomorebiPaperV/SmithCyclic.lean.

```
theorem cyclic_composition (N : ℕ) (hN : 0 < N) (k l : ℕ) (p : Projective) :
    cyclicAction N k (cyclicAction N l p) = cyclicAction N ((k+l)%N) p := by
  unfold cyclicAction
  rw [projective_mul]
  have he : omega N ^ k * omega N ^ l = omega N ^ ((k+l)%N) := by
    rw [← pow_add, pow_eq_pow_mod (k+l) (omega_pow N hN)]
  congr 1
```

This source target establishes the modulo-N composition law. It should not be described as a separate formal proof that the action has exact order N unless the required primitivity and nontriviality converse are established as additional formal declarations. The broader traditional treatment contains further action analysis. Its prose scope is separately recorded.

7.6 Cayley coordinates explain the action

In the pair coordinates $(u-v, u+v)$, the action multiplies the first coordinate by a and leaves the second fixed.

Source: KomorebiPaperV/SmithCyclic.lean.

```
theorem cayley_conjugacy (a : ℂ) (p : ℂ × ℂ) :
    ((action a p).1 - (action a p).2, (action a p).1 + (action a p).2) =
      (a * (p.1-p.2), p.1+p.2) := by
  apply Prod.ext <;> dsimp [action] <;> ring
```

On a finite chart where the denominators are nonzero, this corresponds to rotation or multiplication of the reflection coefficient. The rational impedance formula is

$$z \longmapsto \frac{(1+a)z + (1-a)}{(1-a)z + (1+a)}.$$

A vanishing denominator means the image is the projective point at infinity. Lean's field division is totalized, so a bare identity of division expressions does not by itself assert that a displayed chart exists. The homogeneous action carries the geometry through such poles, while chart composition theorems carry explicit denominator conditions.

7.7 The half-turn swaps zero and infinity

For $N = 2$, $\omega_2 = -1$ and the homogeneous action swaps the two coordinates.

Source: KomorebiPaperV/SmithCyclic.lean.

```
theorem two_phase_swap (p : ℂ × ℂ) : action (omega 2 ^ 1) p = (p.2,p.1) := by
  rw [pow_one, omega_two, half_turn]
```

On the finite nonzero chart this gives $z \mapsto z^{-1}$. At $z = 0$ it maps $[0 : 1]$ to $[1 : 0]$. At infinity it does the reverse. The reciprocal formula is therefore a chart description of a globally defined projective transformation, not a rule that discards poles.

7.8 Dyadic and odd masks factor by CRT

If $N = 2^a M$ with M odd, the two factors are coprime. An integer satisfies a residue condition modulo their product precisely when it satisfies both factor conditions. The source proves the corresponding equality of integer-residue masks.

Source: `KomorebiPaperV/CRT.lean`.

```
theorem dyadic_odd_packet_factorization (a d : ℕ) (hd : Odd d)
    (r : ZMod (2 ^ a * d)) (x : ℤ → V) :
    KomorebiPaperV.packet (fun i : ℤ => (i : ZMod (2 ^ a * d))) r x =
      KomorebiPaperV.packet (fun i : ℤ => (i : ZMod (2 ^ a)))
        (ZMod.chineseRemainder (dyadic_odd_coprime a d hd) r).1
        (KomorebiPaperV.packet (fun i : ℤ => (i : ZMod d))
          (ZMod.chineseRemainder (dyadic_odd_coprime a d hd) r).2 x) :=
  residue_mask_factorization _ _ (dyadic_odd_coprime a d hd) r x
```

This is an exact mask factorization. It does not prove that a particular nonuniform sample allocation is optimal, nor does it provide a minimax sampling theorem. It supplies the arithmetic structure on which more specialized sampling constructions can be built.

8 Trust boundaries and reproduction

8.1 What the inherited audit actually checks

The preserved compiler log records 225 explicit theorem targets and 827 namespace declarations. The audit driver first requires each target to be present as a theorem. It then traverses the `KomorebiPaperV` namespace, rejects unsafe declarations, rejects local axiom and opaque declarations, and collects transitive axiom dependencies.

Only `propext`, `Classical.choice`, and `Quot.sound` are permitted. The audit checks the dependencies of the compiled declarations. It does not prove that English prose is a correct paraphrase of those declarations, that a Python implementation matches a Lean definition, or that an application has supplied a theorem's hypotheses.

The current guide build reconciles each target name with its immutable source location and inherited axiom-output record. It verifies pinned source hashes and performs a lexical scan for proof placeholders and prohibited source constructs. These checks protect provenance and locate obvious source-policy violations. They do not replace elaboration, type checking, or a new kernel traversal.

8.2 Recorded verification

The saved compiler transcript identifies the checked sources and their pinned dependencies. The accompanying reports distinguish that kernel execution from the source checks and finite computations described here.

The recorded computational review ran the twenty exact model tests, comprising 305,933 counted assertions, and all sixteen verifier control methods. It ran the 33 companion pytest tests and the 27 overlapping retained tests with no skips. These finite tests of implementations and models have separate contracts for their tested scope.

8.7 A checklist for using the theorems

Before using a result, identify its ambient type and explicit hypotheses, locate the exact declaration, and check how the application supplies each hypothesis. For an FIR bank, confirm finite Laurent support and delay units. For a transform equality, supply weighted summability. For pruning synthesis, supply conservation. For selector stability, establish the strict gap and joint local-error bound. For a Smith chart, check denominator nonvanishing or use the projective action.

This is the recurring pattern of the formal development: construct the object in the correct space, prove the bridge to the intended model, then use the identity whose hypotheses have actually been supplied.

9 The complete twenty-result correspondence

Each entry gives the scoped formal statement, its principal declarations, and the traditional manuscript locator. The 225-target catalog includes the supporting theorems as well. Principal targets may recur because one synthesis fact supports more than one manuscript statement. These are navigation relationships, not additive theorem counts. Traditional locators use printed Arabic pages. The unnumbered cover and Roman opening pages have separate physical PDF indices, preserved in the companion crosswalk.

9.11 6.2 Several exact edge packets

Traditional locator. Corollary 6.2, final paper p. 12; `result:11`. **Exact reviewed scope.** Finite families of exactly retained jump packets. `KomorebiPaperV.several_known_edges_error`

`KomorebiPaperV/KnownEdge.lean`, line 25.

`KomorebiPaperV.several_known_edges_norm`

`KomorebiPaperV/KnownEdge.lean`, line 38.

9.12 7.1 Packet perturbation bound

Traditional locator. Theorem 7.1, final paper p. 13; `result:12`. **Exact reviewed scope.** Measurable scalar masks in arbitrary measure spaces; extended finite-p norms, and pointwise plus essential supremum bounds. Finite mask and symmetric-difference measures yield the finite real-valued statement. `KomorebiPaperV.MaskPerturbation.indicator_difference_norm`

`KomorebiPaperV/MaskPerturbation.lean`, line 25.

`KomorebiPaperV.MaskPerturbation.finite_p_perturbation`

`KomorebiPaperV/MaskPerturbation.lean`, line 43.

`KomorebiPaperV.MaskPerturbation.pointwise_sup_bound`

`KomorebiPaperV/MaskPerturbation.lean`, line 59.

`KomorebiPaperV.MaskPerturbation.infinity_perturbation`

`KomorebiPaperV/MaskPerturbation.lean`, line 73.

`KomorebiPaperV.MaskPerturbation.full_signal_perturbation`

`KomorebiPaperV/MaskPerturbation.lean`, line 79.

9.13 11.2 Exact synthesis from every complete pruning

Traditional locator. Theorem 11.2, final paper p. 20; `result:13`. **Exact reviewed scope.** Literal finite node sums over covering antichains, with exact operator and applied-signal synthesis under the manuscript conservation hypotheses. `KomorebiPaperV.PruningSums.cutSum_eq_nodeSum`

`KomorebiPaperV/PruningSums.lean`, line 54.

`KomorebiPaperV.PruningSums.antichain_synthesis`

`KomorebiPaperV/PruningSums.lean`, line 81.

`KomorebiPaperV.PruningSums.packet_projector_synthesis`

`KomorebiPaperV/PruningSums.lean`, line 88.

9.14 11.3 Finite globally optimal stable selector

Traditional locator. Theorem 11.3, final paper p. 20; `result:14`. **Exact reviewed scope.** Named non-additive representation/leakage/complexity criterion; attained positive gap when competitors exist, uniform perturbation stability, and singleton case. Every pruning preserves synthesis. `KomorebiPaperV.PruningSums.objective_minimum`

`KomorebiPaperV/PruningSums.lean`, line 134.

`KomorebiPaperV.PruningSums.objective_gap_attained`

`KomorebiPaperV/PruningSums.lean`, line 165.

`KomorebiPaperV.PruningSums.objective_stability`

`KomorebiPaperV/PruningSums.lean`, line 148.

`KomorebiPaperV.PruningSums.singleton_selector`

`KomorebiPaperV/PruningSums.lean`, line 158.

`KomorebiPaperV.PruningSums.packet_projector_synthesis`

`KomorebiPaperV/PruningSums.lean`, line 88.

9.15 11.4 Dynamic-programming best packet basis

Traditional locator. Theorem 11.4, final paper p. 21; `result:15`. **Exact reviewed scope.** Cached bottom-up evaluator equals the global selector; stop on ties. One comparison per internal node; at most 3*node-count unit operations for visits/comparisons/value additions with node costs supplied. Not a Lean runtime or scalar-cost evaluation bound. `KomorebiPaperV.PruningAlgorithm.solve_correct`

`KomorebiPaperV/PruningAlgorithm.lean`, line 36.

`KomorebiPaperV.PruningAlgorithm.solve_comparisons`

`KomorebiPaperV/PruningAlgorithm.lean`, line 52.

`KomorebiPaperV.PruningAlgorithm.solve_visits`

`KomorebiPaperV/PruningAlgorithm.lean`, line 61.

`KomorebiPaperV.PruningAlgorithm.solve_additions`

`KomorebiPaperV/PruningAlgorithm.lean`, line 69.

`KomorebiPaperV.PruningAlgorithm.solve_linear_work`

`KomorebiPaperV/PruningAlgorithm.lean`, line 89.

`KomorebiPaperV.PruningAlgorithm.computed_antichain_optimal`

`KomorebiPaperV/PruningAlgorithm.lean`, line 97.

9.16 11.5 Local perturbation certificate

Traditional locator. Corollary 11.5, final paper p. 21; `result:16`. **Exact reviewed scope.** Exact maximum antichain error envelope and strict-gap stability; probability transfer from a joint local-error event is proved in PruningAlgorithm. `KomorebiPaperV.PruningSums.antichain_perturbation`

`KomorebiPaperV/PruningSums.lean`, line 108.

`KomorebiPaperV.PruningSums.antichain_envelope_attained`

`KomorebiPaperV/PruningSums.lean`, line 115.

`KomorebiPaperV.PruningSums.antichain_selector_stable`

`KomorebiPaperV/PruningSums.lean`, line 120.

`KomorebiPaperV.PruningAlgorithm.antichain_probability`

`KomorebiPaperV/PruningAlgorithm.lean`, line 102.

9.17 12.1 Cyclic product law

Traditional locator. Theorem 12.1, final paper p. 24; `result:17`. **Exact reviewed scope.** Formal power-series cyclic product and literal q-tuple power formula over commutative semirings, including q=0. Analytic interpretations apply on their convergence domains; no arbitrary divergent evaluation is asserted. `KomorebiPaperV.CyclicSeries.cyclic_product_law`

`KomorebiPaperV/CyclicSeries.lean`, line 126.

`KomorebiPaperV.CyclicSeries.cyclic_power_law`

`KomorebiPaperV/CyclicSeries.lean`, line 195.

9.18 13.2 Polyphase Möbius action

Traditional locator. Theorem 13.2, final paper p. 26; `result:18`. **Exact reviewed scope.** Explicit exponential root of unity and modulo-N action on the projective quotient of nonzero homogeneous pairs; Cayley conjugacy and the finite-chart formula. `KomorebiPaperV.SmithCyclic.omega_pow`

`KomorebiPaperV/SmithCyclic.lean`, line 12.

`KomorebiPaperV.SmithCyclic.cyclic_composition`

`KomorebiPaperV/SmithCyclic.lean`, line 78.

`KomorebiPaperV.SmithCyclic.cayley_conjugacy`

`KomorebiPaperV/SmithCyclic.lean`, line 87.

`KomorebiPaperV.SmithCyclic.cyclic_chart`

`KomorebiPaperV/SmithCyclic.lean`, line 92.

`KomorebiPaperV.SmithCyclic.projective_mul`

`KomorebiPaperV/SmithCyclic.lean`, line 56.

9.19 13.3 Impedance–admittance is the two-phase split

Traditional locator. Corollary 13.3, final paper p. 26; `result:19`. **Exact reviewed scope.** The N=2 phase is -1; its action swaps homogeneous coordinates, exchanging zero/infinity and giving inverse impedance on the nonzero chart. `KomorebiPaperV.SmithCyclic.omega_two`

`KomorebiPaperV/SmithCyclic.lean`, line 19.

`KomorebiPaperV.SmithCyclic.two_phase_swap`

`KomorebiPaperV/SmithCyclic.lean`, line 97.

`KomorebiPaperV.SmithCyclic.two_phase_impedance_admittance`

`KomorebiPaperV/SmithCyclic.lean`, line 100.

9.20 14.1 Dyadic–odd packet factorization

Traditional locator. Proposition 14.1, final paper p. 29; `result:20`. **Exact reviewed scope.** Signed integer CRT residue masks and dyadic-odd factorization. `KomorebiPaperV.CRT.residue_mask_factorization`

`KomorebiPaperV/CRT.lean`, line 20.

`KomorebiPaperV.CRT.dyadic_odd_packet_factorization`

`KomorebiPaperV/CRT.lean`, line 34.

10 The broader traditional developments

The mathematical text preserves two substantial source strands. Part I contains the twenty-result formal core. Part II contains sixty-three proof records from the broader Annals development. Together they produce 83 proof records, with overlap in mathematical content. The number 83 counts presented proofs. It does not replace the twenty-result Lean denominator or establish 83 independent new results. The table below connects groups of Part II developments to nearby formal-core concepts. "Nearby" is a reading aid. It does not assert a formal reduction or that the stated Part II result has been compiled in Lean.

Part II topic	Nearest formal core	Additional boundary
Operator partitions and refinement	Results 1.1–2.3, `HilbertPackets`	Broader operator settings or frames require their own assumptions and proofs.
Polyphase symbols and banks	Results 3.1–4.3, `FilterBank`, `ZTransform`	Unit-circle and L^2 boundary interpretations must be distinguished from off-circle weighted summability.
Frame trees and adaptive objectives	Results 11.2–11.5, `PruningSums`	Local frame bounds are nonnegative. The dynamic-programming result applies to additive costs.
Known edges, masks, and commutators	Results 6.1–7.1, `KnownEdge`, `MaskPerturbation`	A commutator using Q as an operator requires bounded linearity. Cancellation alone does not.
Boundary tubes and edge geometry	Mask perturbation theorem 7.1	Tube estimates use their local range $\delta < \delta_0$. Geometric constants and regularity are additional data.
Continuous Haar edge models	Discrete Haar results 4.2 and 5.1	Half-line step functions need care: their wavelet coefficients can be used even when the steps themselves are not in $L^2(\mathbb{R})$.
Random or asymptotic selection	Finite joint-event transfer 11.5	Probability bounds tending to one establish convergence in probability. Almost sure claims need stronger evidence.
Nonlinear cyclic products	Result 12.1, `CyclicSeries`	Analytic evaluation and stronger functional-analytic claims are additional to formal coefficient identities.
Smith geometry and sampling	Results 13.2–14.1, `SmithCyclic`, `CRT`	The formal composition law alone is not a target proving exact-order converse or optimal sampling.

The final traditional audit records the precise scope repairs applied to Part II. This guide preserves the resulting hypotheses in its discussion. It does not incorporate altered claims into unchanged Lean targets. The following inventory provides a locator for every Part II proof record and explicitly keeps its formal status separate.

10.1 All sixty-three Part II proof records

Every row below has status: prose proof; no additional Lean claim. The final E-prefixed result number and page refer to the combined traditional paper. The nearest-core column identifies related reading only.

10.2 Open conjecture locators

Stable edge-packet recovery. Conjecture 7.2, final traditional p. 13; `core:record:17`. Open; excluded from the twenty-result formal contract.

Edge-packet approximation class. Conjecture 15.1, final traditional p. 29; `core:record:35`. Open; excluded from the twenty-result formal contract.

11 All 225 theorem targets

This catalog reproduces every qualified target from the saved candidate_contract.json, grouped by its actual source module. Line numbers refer to the immutable bundled Lean sources. Every target was reconciled with its declaration line, audit directive, and inherited axiom-output record. This reconciliation does not perform Lean elaboration.

11.1 BinaryAdaptive: 6 targets

Source: `formalization/lean/KomorebiPaperV/BinaryAdaptive.lean`.

`KomorebiPaperV.Binary.cutSum_eq_root`
Source line 36; theorem.

`KomorebiPaperV.Binary.value_le_cost`
Source line 59; theorem.

`KomorebiPaperV.Binary.best_cost`
Source line 69; theorem.

`KomorebiPaperV.Binary.best_is_global_minimum`
Source line 79; theorem.

`KomorebiPaperV.Binary.root_le_envelope`
Source line 88; theorem.

`KomorebiPaperV.Binary.cut_perturbation`
Source line 94; theorem.

11.2 CRT: 4 targets

Source: `formalization/lean/KomorebiPaperV/CRT.lean`.

`KomorebiPaperV.CRT.residue_pair_iff`
Source line 13; theorem.

`KomorebiPaperV.CRT.residue_mask_factorization`
Source line 20; theorem.

`KomorebiPaperV.CRT.dyadic_odd_coprime`
Source line 31; theorem.

`KomorebiPaperV.CRT.dyadic_odd_packet_factorization`
Source line 34; theorem.

11.3 CompletePrunings: 15 targets

Source: `formalization/lean/KomorebiPaperV/CompletePrunings.lean`.

`KomorebiPaperV.CompletePrunings.terminal_exists`
Source line 36; theorem.

`KomorebiPaperV.CompletePrunings.node_on_terminal`
Source line 43; theorem.

`KomorebiPaperV.CompletePrunings.selected_stop_iff`

Source line 52; theorem.

Source line 120; theorem.

`KomorebiPaperV.CompletePrunings.complete_root_unique`
Source line 140; theorem.

`KomorebiPaperV.CompletePrunings.complete_child`
Source line 149; theorem.

`KomorebiPaperV.CompletePrunings.complete_has_cut`
Source line 164; theorem.

`KomorebiPaperV.CompletePrunings.cut_ext`
Source line 192; theorem.

`KomorebiPaperV.CompletePrunings.complete_pruning_finite`
Source line 226; theorem.

`KomorebiPaperV.CompletePrunings.complete_pruning_minimum`
Source line 230; theorem.

11.4 CyclicSeries: 15 targets

Source: `formalization/lean/KomorebiPaperV/CyclicSeries.lean`.

`KomorebiPaperV.CyclicSeries.coeff_cyclicProjector`
Source line 33; theorem.

`KomorebiPaperV.CyclicSeries.cyclicProjector_idempotent`
Source line 38; theorem.

`KomorebiPaperV.CyclicSeries.cyclicProjector_orthogonal`
Source line 43; theorem.

`KomorebiPaperV.CyclicSeries.cyclicProjector_eq_zero_of_residue_ne`
Source line 51; theorem.

`KomorebiPaperV.CyclicSeries.cyclicProjector_eq_of_mod_eq`
Source line 56; theorem.

`KomorebiPaperV.CyclicSeries.cyclicProjector_add`
Source line 62; theorem.

`KomorebiPaperV.CyclicSeries.cyclicProjector_sum`

Source line 67; theorem.

`KomorebiPaperV.CyclicSeries.sum_cyclicProjector`
Source line 78; theorem.

`KomorebiPaperV.CyclicSeries.cyclicProjector_product_packet`
Source line 92; theorem.

`KomorebiPaperV.CyclicSeries.cyclicProjector_product_other`
Source line 118; theorem.

`KomorebiPaperV.CyclicSeries.cyclic_product_law`
Source line 126; theorem.

`KomorebiPaperV.CyclicSeries.pure_finite_product`
Source line 159; theorem.

`KomorebiPaperV.CyclicSeries.project_finite_product`
Source line 177; theorem.

`KomorebiPaperV.CyclicSeries.sum_fin_projector`
Source line 189; theorem.

`KomorebiPaperV.CyclicSeries.cyclic_power_law`
Source line 195; theorem.

11.5 FIRTransfer: 6 targets

Source: `formalization/lean/KomorebiPaperV/FIRTransfer.lean`.

`KomorebiPaperV.FIRTransfer.tapEquiv_symm`
Source line 34; theorem.

`KomorebiPaperV.FIRTransfer.tapIndex_equiv`
Source line 41; theorem.

`KomorebiPaperV.FIRTransfer.transfer_address`
Source line 48; theorem.

`KomorebiPaperV.FIRTransfer.fir_reindex`
Source line 65; theorem.

`KomorebiPaperV.FIRTransfer.sum_pair_fiber`
Source line 82; theorem.

`KomorebiPaperV.FIRTransfer.fir_polyphase_transfer`
Source line 96; theorem.

11.6 FilterBank: 13 targets

Source: `formalization/lean/KomorebiPaperV/FilterBank.lean`.

`KomorebiPaperV.FilterBank.act_apply`
Source line 31; theorem.

`KomorebiPaperV.FilterBank.act_is_fir`
Source line 36; theorem.

`KomorebiPaperV.FilterBank.act_impulse`

Source line 43; theorem.

`KomorebiPaperV.FilterBank.act_single`
Source line 50; theorem.

`KomorebiPaperV.FilterBank.evalZ_apply`
Source line 65; theorem.

`KomorebiPaperV.FilterBank.filter_transform`
Source line 70; theorem.

`KomorebiPaperV.FilterBank.bank_mul`
Source line 84; theorem.

`KomorebiPaperV.FilterBank.bank_impulse`
Source line 93; theorem.

`KomorebiPaperV.FilterBank.bank_faithful`
Source line 104; theorem.

`KomorebiPaperV.FilterBank.gain_delay_action`
Source line 121; theorem.

`KomorebiPaperV.FilterBank.perfect_reconstruction_iff`
Source line 133; theorem.

`KomorebiPaperV.FilterBank.bank_transform`
Source line 147; theorem.

`KomorebiPaperV.FilterBank.original_sample_delay`
Source line 155; theorem.

11.7 FiniteAdaptive: 18 targets

Source: `formalization/lean/KomorebiPaperV/FiniteAdaptive.lean`.

`KomorebiPaperV.FiniteAdaptive.cutSum_eq_root`
Source line 39; theorem.

`KomorebiPaperV.FiniteAdaptive.cutSum_eq_identity`
Source line 53; theorem.

`KomorebiPaperV.FiniteAdaptive.pathHits_one`
Source line 67; theorem.

`KomorebiPaperV.FiniteAdaptive.arbitrary_objective_minimum`
Source line 107; theorem.

`KomorebiPaperV.FiniteAdaptive.strict_minimum_positive_gap`
Source line 114; theorem.

`KomorebiPaperV.FiniteAdaptive.value_le_cost`
Source line 136; theorem.

`KomorebiPaperV.FiniteAdaptive.best_cost`
Source line 146; theorem.

`KomorebiPaperV.FiniteAdaptive.best_is_global_minimum`
Source line 156; theorem.

`KomorebiPaperV.FiniteAdaptive.best_preserves_synthesis`

Source line 161; theorem.

`KomorebiPaperV.FiniteAdaptive.stop_on_tie`
Source line 165; theorem.

`KomorebiPaperV.FiniteAdaptive.root_le_envelope`
Source line 174; theorem.

12 Source architecture and exact dependency pins

The import list below is extracted from the 25 Lean files: the 23 proof modules, the aggregate import file, and the audit driver. Imports beginning with `Mathlib` are external mathematical dependencies. Imports beginning with `KomorebiPaperV` are local. The import graph describes compilation dependencies, which can be broader than the logical dependency of an individual theorem.

Transfer Semigroups and Memory

The formal companion to Chapter VI explains the declared hypotheses, theorem correspondences and evidence boundaries.

IN THIS COMPANION

Formal companion 1993

Return to Chapter VI

How to use this volume

A guide to the actual formal development. 33 scoped manuscript results. 341 supporting theorem targets. 47 proof modules. The eleven chapters explain the mathematical interfaces and how to reproduce their recorded evidence. The complete ledgers then give exact declarations, source locations, imports, and nine dependency pins. This guide preserves 48 exact Lean excerpts. The broader traditional development has 142 theorem-like result records and 140 written proof bodies across overlapping branches. Its extra written results do not extend the 33-result formal contract. Three continuum conjectures remain open. Kernel execution evidence comes from the recorded thirty-three-result formal-core build. Source identities, declaration locations, axiom records and finite computations are tracked separately. This reading guide does not claim a new kernel execution.

1 How to read the formal companion

The Lean project formalizes the explicitly scoped mathematical core of Chapter VI. It turns an equation such as $Ce^{tA} = e^{tB}C$ into a statement with named spaces, scalar fields, operator types, and hypotheses. This guide follows those interfaces. It explains how the formal pieces fit together and where the mathematical text goes beyond them.

The formal ledger records all 33 scoped results as complete. The source contract names 341 explicit theorem declarations across 47 proof modules. The saved compiler and namespace audit reports record that 782 declarations were inspected in the project namespace. These counts measure manuscript endpoints, named theorem declarations, files and the wider namespace. None counts independent new mathematical discoveries.

The traditional monograph preserves the larger written development in Parts I through III, followed by the worked atlas in Part IV. Part I gives the formal core. Part II retains the strengthened exposition. Part III retains earlier results not subsumed by that exposition and the bounded Banach operator material migrated from Chapter IV. The theorem-like result records across these parts include conceptual overlap. Formal completion remains attached to the 33 specific Part I ledger entries.

Read one endpoint through its whole interface

Start with the statement and proof in the traditional volume. Locate its numbered row in the 33-result ledger. Read the surrounding variables in the original Lean module, then compare the declaration's hypotheses and conclusion with the mathematical statement. Finally, identify whether the evidence is an inherited kernel record, a current source reconciliation, or a bounded computation. These steps answer different questions.

1.1 Three forms of evidence

Evidence	What it establishes here
Inherited kernel evidence	The saved build and axiom audit for the pinned source and de- pendencies. This guide does not claim a new Lean compilation.
Recorded source and computational checks	Source hashes, target inventories, verifier controls, and available finite examples were rerun in the recorded monograph review. These are not kernel checking or universal proofs.
Mathematical correspondence	The relationship between prose, hypotheses, definitions, ordinary real/complex specializations, and theorem interfaces is a manual review responsibility.

The source report explicitly records `full_paper_formalized: false`. That remains correct even though `all_scoped_results_complete: true` is recorded for the recorded kernel run. Figures, explanatory prose, broader extensions, and three open conjectures are not swallowed by the scoped denominator.

1.2 A practical reading route

Read the matching traditional argument first, use the visual guide to inspect a finite example, and then find its ledger entry in Section 12. Follow the named endpoint to a source excerpt or the complete declaration catalog. Check the ambient variables at the top of the original module before attempting to reuse an excerpt. A snippet does not repeat every `variable`, `open`, instance, or imported notation in its file.

All displayed Lean blocks are exact contiguous source excerpts from the preserved production modules. Raw UTF-8 copies and source hashes accompany the editable guide. Font fallback in the PDF changes rendering only. The snippets are reading excerpts, not independent programs that can be compiled without their original context.

1.3 The notation that matters most

Lean notation	Mathematical reading
`Matrix I J ℂ`	A complex matrix with rows indexed by I and columns by J. Different index types permit rectangular maps.
`E →L[ℂ] F`	A bounded complex linear map from E to F. Completeness and inner-product assumptions come from ambient instances.
`C.comp A`	Composition $C \circ A$: apply A first, then C.
`Module.End ℂ V`	A complex linear endomorphism of V. Finite dimension is a separate hypothesis.
`IntegrableOn f (Ioi 0)`	Bochner integrability of f over $(0, \infty)$ with the stated measure, here ordinarily Lebesgue measure.
`Tendsto f atTop (𝓝 0)`	The limit of $f(t)$ is zero as t tends to $+\infty$.
`0 ≤ A`	Positivity in the operator or C^*-algebra order in the fractional modules. This is not entrywise matrix positivity.
`∀ i j, 0 ≤ K i j`	Entrywise nonnegativity of a finite real matrix.
`Ring.inverse`	A total inverse operation. The surrounding proof must establish the required invertibility before an inverse formula has its intended analytic meaning.

1.4 Common mistakes that the interfaces prevent

Column-stochastic transition matrices act on probability columns. Observable propagation uses the transpose. Probability aggregation is a rectangular mass-summing map. A weighted conditional expectation is a square projector on observables. Their identities are related but their types differ. Similarly, e^{tA} describes a general generator, while a positive fractional operator produces $e^{-tA^{\alpha}}$. The minus sign changes the Duhamel defect in the fractional semigroup theorem.

Zero evidence, one coarse packet, a zero-dimensional space, a zero spectral value, and a nonnormal hidden generator are not interchangeable edge cases. Each belongs to a particular interface. This guide identifies the relevant hypothesis at the point where it is used.

2 Semigroups and rectangular defects

The algebraic layer begins with finite packet blocks P_bAP_a in a ring. It proves reconstruction, multiplication through intermediate packets, and telescoping formulas without assuming stochasticity or self-adjointness. The analytic layer then uses the actual algebra exponential. The definition is short because convergence and differentiation are supplied by the imported analysis library and the ambient Banach-algebra structure.

Source: KomorebiPaperVI/Semigroups.lean.

```
noncomputable def transfer (A : R) (t : ℝ) : R := exp (t • A)
```

Source: KomorebiPaperVI/Semigroups.lean.

```
theorem transfer_add (A : R) (s t : ℝ) : transfer A (s+t) = transfer A s*transfer A t := by
  let : NormedAlgebra ℚ R := NormedAlgebra.restrictScalars ℚ ℝ R
  dsimp [transfer]
  rw [add_smul]
  exact exp_add_of_commute (((Commute.refl A).smul_left s).smul_right t)
```

2.1 Reconstruction is stronger than a diagram

If $\sum_a P_a = 1$, every input/output block participates in reconstruction. Idempotence supplies the block product identity. Pairwise reduction requires additional hypotheses on the off-diagonal generator blocks. It does not follow merely from writing A in blocks. The endpoint for core 2.1 uses the actual exponential law:

Source: KomorebiPaperVI/Semigroups.lean.

```
theorem exponential_packet_convolution {I : Type*} [Fintype I]
    (P : I → R) (hP : ∑ i, P i=1) (hid : ∀ i, P i*P i=P i)
    (A : R) (s t : ℝ) (b a : I) :
    Algebra.block P (transfer A (s+t)) b a =
      ∑ c, Algebra.block P (transfer A s) b c*Algebra.block P (transfer A t) c a :=
  Algebra.packet_semigroup_convolution P hP hid (transfer A) (transfer_add A) s t b a
```

For core 2.2, `ReducingPackets.generator_commutes` derives commutation from vanishing off-diagonal generator blocks. The subsequent theorems prove vanishing exponential cross blocks and equality with the compressed evolution. A projection that is not reducing can produce a memory term when its complement is eliminated. The later memory chapter explains why.

2.2 The domain of the refinement map is explicit

Let $A : E \to E$, $B : F \to F$, and $C : E \to F$. Define $D = CA - BC$. The real Banach-space theorem differentiates $e^{(t-r)B}Ce^{rA}$ and integrates that derivative. Rectangular types enforce the order of every composition.

Source: `KomorebiPaperVI/Semigroups.lean`.

```
theorem duhamel_rectangular (A : E →L[ℝ] E) (B : F →L[ℝ] F)
    (C : E →L[ℝ] F) (t : ℝ) :
    C.comp (transfer A t)-(transfer B t).comp C =
      ∫ r in 0..t, (transfer B (t-r)).comp ((C.comp A-B.comp C).comp (transfer A r)) := by
  have hc : Continuous (fun r => (transfer B (t-r)).comp
      ((C.comp A-B.comp C).comp (transfer A r))) := by
    fun_prop
  have h := intervalIntegral.integral_eq_sub_of_hasDerivAt
    (fun r _ => duhamel_integrand_derivative A B C t r) (hc.intervalIntegrable 0 t)
  simpa [transfer_zero, ContinuousLinearMap.one_def] using h.symm
```

The identity itself is valid for every real t as an oriented interval integral. Bounds such as $\|Ce^{tA} - e^{tB}C\| \le t\|D\|$ additionally assume $t \ge 0$ and contraction estimates for both semigroups. The general growth estimate lives in `OperatorBounds.growth_duhamel_bound`. The exact case specializes the same identity to $D = 0$:

Source: `KomorebiPaperVI/Semigroups.lean`.

```
theorem exact_rectangular_intertwining (A : E →L[ℝ] E) (B : F →L[ℝ] F)
    (C : E →L[ℝ] F) (h : C.comp A=B.comp C) (t : ℝ) :
    C.comp (transfer A t)=(transfer B t).comp C := by
  have hd := duhamel_rectangular A B C t
  simp only [h, sub_self, ContinuousLinearMap.zero_comp, ContinuousLinearMap.comp_zero,
    intervalIntegral.integral_zero] at hd
  exact sub_eq_zero.mp hd
```

2.3 Discrete time and resolvents

Core 5.2 is an exact finite sum before a norm estimate is applied. Horizon zero is included by the empty sum. Its source uses ring-valued literal matrices with independently typed row and column spaces:

Source: `KomorebiPaperVI/Algebra.lean`.

```
theorem finite_horizon_defect (C : Matrix m n R) (A : Matrix n n R) (B : Matrix m m R)
    (k : ℕ) :
    C*A^k-B^k*C = ∑ j ∈ Finset.range k, B^(k-1-j)*(C*A-B*C)*A^j := by
  induction k with
  | zero => simp
  | succ k ih =>
    rw [Finset.sum_range_succ]
    have hs : (∑ j ∈ Finset.range k, B^(k+1-1-j)*(C*A-B*C)*A^j) =
        B*(∑ j ∈ Finset.range k, B^(k-1-j)*(C*A-B*C)*A^j) := by
      rw [Matrix.mul_sum]
```

```
      apply Finset.sum_congr rfl
      intro j hj
      have hjk := Finset.mem_range.mp hj
      have he : k+1-1-j = (k-1-j)+1 := by omega
      rw [he, pow_succ']
      simp only [Matrix.mul_assoc]
    rw [hs, ← ih]
    simp only [Nat.add_sub_cancel, Nat.sub_self, pow_zero, Matrix.one_mul]
    simp only [pow_succ', Matrix.mul_sub, Matrix.sub_mul, Matrix.mul_assoc]
    abel
```

The resolvent identity requires one inverse equation on each side. This is deliberate: the proof does not invoke a vague invertibility claim when only the relevant cancellations are needed. The scalar must commute with the entries of C in the general ring statement.

Source: `KomorebiPaperVI/Algebra.lean`.

```
theorem rectangular_resolvent_identity (C : Matrix m n R)
    (A : Matrix n n R) (B : Matrix m m R)
    (Rf : Matrix n n R) (Rc : Matrix m m R) (z : R)
    (hz : ∀ i j, z*C i j = C i j*z)
    (hf : (Matrix.scalar n z-A)*Rf=1)
    (hc : Rc*(Matrix.scalar m z-B)=1) :
    C*Rf-Rc*C=Rc*(C*A-B*C)*Rf := by
  have hzC : Matrix.scalar m z*C=C*Matrix.scalar n z := by
    ext i j
    simpa using hz i j

    rw [Matrix.sub_mul, Matrix.mul_sub, hzC]
    abel
  rw [hd, Matrix.mul_sub, Matrix.sub_mul]
  simp only [← Matrix.mul_assoc, hc, Matrix.one_mul]
  rw [Matrix.mul_assoc (Rc*C), hf, Matrix.mul_one]
```

For ordinary complex matrices the scalar commutation is automatic. For core 3.3 the specified inverse equations are supplied by the actual resolvents. The broad Banach-space and contour extensions in the traditional chapter have their own domains and hypotheses. The literal matrix interface is the formal endpoint recorded in this ledger entry.

3 Markov mass and conditional expectation

3.1 Column conservation

`MarkovSemigroup` proves nonnegativity of the actual matrix exponential by shifting a Metzler generator by a scalar identity, expanding a nonnegative matrix exponential, and then undoing the scalar shift. Conservation follows from zero column sums of the generator. The final probability statement combines these two independent facts.

Source: `KomorebiPaperVI/MarkovSemigroup.lean`.

```
theorem markov_probability (Q : Matrix I I ℝ) (hpos : ∀ i j, i≠j → 0 ≤ Q i j)
    (hcol : ∀ j, ∑ i, Q i j=0) (p : I → ℝ) (hp : ∀ i, 0 ≤ p i)
    (hpsum : ∑ i, p i=1) (t : ℝ) (ht : 0 ≤ t) :
    (∀ i, 0 ≤ (exp (t • Q)).mulVec p i) ∧ ∑ i, (exp (t • Q)).mulVec p i=1 := by
  constructor
  · intro i
    exact Finset.sum_nonneg (fun j _ => mul_nonneg (markov_nonnegative Q hpos t ht i j) (hp j))
  · simp only [Matrix.mulVec,dotProduct,Finset.sum_comm,← Finset.sum_mul,markov_column_sum Q hcol,
      one_mul,hpsum]
```

Here Q_{ij} is the rate from state j to state i. Off-diagonal nonnegativity and zero column sums are the generator hypotheses. The condition $t \geq 0$ is essential for the positivity argument. Exact discrete lumpability is core 5.1's rectangular identity $CK^n = \bar{K}^n C$. The complete quotient obstruction and detailed coordinate characterization in Part II are related written results, not additional completed Lean ledger entries.

3.2 Weighted projection on observables

For a partition map $f : I \to A$, `Coarsening.coarsen` sums probability mass over fibers. In contrast, `ConditionalExpectation.expect` returns a function on the original fine space. It averages an observable within each fiber with respect to finite weights p_i. Strict positivity guarantees that the occupied fiber denominator at each fine point is nonzero.

Source: `KomorebiPaperVI/ConditionalExpectation.lean`.

```
theorem expect_idempotent (f : I → A) (p : I → ℝ) (hp : ∀ i, 0 < p i) (v : I → ℂ) :
    expect f p (expect f p v)=expect f p v :=
  expect_constant f p hp (average f p v)
```

The source also proves that the range is exactly the block-constant functions and that the expectation equals a literal kernel matrix applied to the observable. Self-adjointness is with respect to the weighted inner product, not ordinarily the unweighted Euclidean inner product:

Source: `KomorebiPaperVI/ConditionalExpectation.lean`.

```
theorem expect_self_adjoint (f : I → A) (p : I → ℝ) (v w : I → ℂ) :
    weightedInner p (expect f p v) w=weightedInner p v (expect f p w) := by
  rw [expect_matrix,expect_matrix]
  simp only [weightedInner,Matrix.mulVec,dotProduct,Finset.mul_sum,Finset.sum_mul,
```

```
    map_sum,map_mul]
  rw [Finset.sum_comm]
  apply Finset.sum_congr rfl
  intro i _
  apply Finset.sum_congr rfl
  intro j _
  have h := kernel_weighted_symmetry f p j i
  calc
    _ = ((p j:ℂ)*kernel f p j i)*v i*conj (w j) := by ring
    _ = _ := by rw [h]; ring
```

The displayed self-adjoint identity is algebraic and its signature has no positivity premise. Calling the pairing a positive-definite inner product, or deriving range separation from it, uses the strict positivity hypotheses elsewhere in the module. Reuse the endpoint matching the intended claim rather than adding an interpretation that its type does not supply.

3.3 Towers and martingale packets

Composing $f : I \to A$ with $g : A \to B$ makes a coarser partition. Both products of the corresponding conditional kernels equal the coarse kernel:

Source: `KomorebiPaperVI/ConditionalTowers.lean`.

```
theorem conditional_kernel_product (f : I → A) (g : A → B) (p : I → ℝ)
    (hp : ∀ i, 0 < p i) :
    kernel (g ∘ f) p*kernel f p=kernel (g ∘ f) p ∧
      kernel f p*kernel (g ∘ f) p=kernel (g ∘ f) p := by
  constructor
  · apply Matrix.mulVec_injective
    funext v
    rw [← Matrix.mulVec_mulVec,← expect_matrix,← expect_matrix,coarse_after_fine f g p
     ↪ hp,expect_matrix]
  · apply Matrix.mulVec_injective
    funext v
    rw [← Matrix.mulVec_mulVec,← expect_matrix,← expect_matrix,fine_after_coarse f g p
     ↪ hp,expect_matrix]
```

The module extends this to arbitrary pairs in a nested family: the product is the kernel at the coarser index. `MartingalePackets` then supplies the abstract difference-projector algebra, and `ConditionalTowers` applies it to concrete kernels. The differences are pairwise annihilating idempotents and sum to the terminal projector. The formal scope is finite weighted conditional expectation. A general measure-theoretic conditional-expectation tower is a separate classical extension in the traditional exposition.

4 Bayesian normalization, sufficiency, and flow

4.1 An equation is not a probability claim

Lean defines the posterior by a total real division. This makes the expression meaningful as a term even when evidence is zero. Theorems asserting unit mass or probability preservation require nonzero or positive evidence explicitly. The basic definition is:

Source: KomorebiPaperVI/FiniteBayes.lean.

```
noncomputable def update (p l : I → ℝ) (i : I) : ℝ := l i*p i / evidence p l
def l1 (p : I → ℝ) : ℝ := ∑ i, |p i|
```

Core 7.1 proves composition of two likelihood updates with both the first evidence and the combined evidence nonzero. The proof rewrites sequential evidence and then performs field algebra.

Source: KomorebiPaperVI/FiniteBayes.lean.

```
theorem posterior_composition (p l k : I → ℝ) (hz : evidence p l ≠ 0)
    (hzk : evidence p (fun i => l i*k i) ≠ 0) :
    update (update p l) k = update p (fun i => l i*k i) := by
  funext i
  rw [update, sequential_evidence]
  dsimp [update]
  field_simp
```

An application with nonnegative priors and likelihoods must establish positive evidence before using probability interpretations. Normalization does not manufacture an observation with positive probability.

4.2 Perturbation has a denominator

The weighted ℓ^1 likelihood error is divided by the minimum of the two positive evidences. This gives a usable stability estimate while exposing its sensitivity to nearly impossible observations.

Source: KomorebiPaperVI/FiniteBayes.lean.

```
theorem likelihood_perturbation_bound (p l k : I → ℝ)
    (hp : ∀ i, 0 ≤ p i) (_hl : ∀ i, 0 ≤ l i) (hk : ∀ i, 0 ≤ k i)
    (hZl : 0 < evidence p l) (hZk : 0 < evidence p k) :
    l1 (fun i => update p l i-update p k i) ≤
      2*(∑ i, |l i-k i| *p i)/min (evidence p l) (evidence p k) := by
  have he : l1 (fun i => l i*p i-k i*p i) = ∑ i, |l i-k i| *p i := by
    simp only [l1, ← sub_mul, abs_mul, abs_of_nonneg (hp _)]
  have h := normalized_l1_bound_left (fun i => l i*p i) (fun i => k i*p i)
    (fun i => mul_nonneg (hk i) (hp i)) hZl hZk
  change l1 (fun i => update p l i-update p k i) ≤
    2*l1 (fun i => l i*p i-k i*p i)/evidence p l at h
  rw [he] at h
  exact h.trans (div_le_div_of_nonneg_left
    (mul_nonneg (by norm_num) (Finset.sum_nonneg (fun i _ => mul_nonneg (abs_nonneg _) (hp i))))
    (lt_min hZl hZk) (min_le_left _ _))
```

The finite numerical examples can check this inequality for chosen data. They do not replace the universally quantified source theorem or supply an evidence lower bound for a different model.

4.3 Effective likelihood and fixed coarse likelihood

Given a prior p, the effective coarse likelihood averages the fine likelihood within each fiber using that prior. The factorization theorem includes zero-prior-mass fibers. The proof separates these cases rather than silently dividing by their mass.

Source: `KomorebiPaperVI/Coarsening.lean`.

```
theorem effective_factorization (f : I → A) (p l : I → ℝ) (hp : ∀ i, 0 ≤ p i) :
    coarsen f (update p l) = update (coarsen f p) (effective f p l) := by
  rw [coarsen_posterior]
  funext a
  simp only [update, effective_weight f p l hp, effective_evidence f p l hp]
```

The effective likelihood depends on the prior. A single prescribed coarse likelihood that works for every prior is a stronger requirement. The necessary-and-sufficient theorem derives that requirement using actual two-point priors. With at least two coarse states, surjectivity, and strict positivity, fine likelihoods must agree with the pulled-back coarse likelihood up to one positive global scale:

Source: `KomorebiPaperVI/BayesianNecessity.lean`.

```
theorem refinement_iff (f : I → A) (hf : Function.Surjective f) [Nontrivial A]
    (l : I → ℝ) (k : A → ℝ) (hl : ∀ i, 0 < l i) (hk : ∀ a, 0 < k a) :
    AllPriorCommutes f l k ↔ ∃ c : ℝ, 0 < c ∧ ∀ i, l i=c*k (f i) := by
  constructor
  · intro h
    obtain ⟨a⟩ := (inferInstance : Nonempty A)
    obtain ⟨i,hi⟩ := hf a
    refine ⟨l i/k (f i), div_pos (hl i) (hk (f i)), ?_⟩
    intro j
    have he := all_packet_ratio f hf l k hl hk h j i
    apply (eq_div_iff (ne_of_gt (hk (f i)))).mpr at he
    calc
      l j = (l i*k (f j))/k (f i) := he
      _ = _ := by ring
  · rintro ⟨c,hc,he⟩ p hp
    have heq : l=fun i => c*k (f i) := funext he
    rw [heq]
    exact scaled_blockwise_sufficiency f p k c hc.ne'
      (positive_evidence p (k ∘ f) hp (fun i => hk (f i))).ne'
```

The nontriviality assumption is part of the mathematics. If all mass is sent to one packet, every valid posterior aggregates to the unique unit probability, so commutation no longer forces likelihood constancy:

Source: KomorebiPaperVI/BayesianTowers.lean.

```
theorem singleton_commutes (f : I → A) (l : I → ℝ) (k : A → ℝ)
    (hl : ∀ i, 0 < l i) (hk : ∀ a, 0 < k a) [Subsingleton A] :
    AllPriorCommutes f l k := by
  intro p hp
  funext a
  have hs (v : A → ℝ) : mass v=v a :=
    Finset.sum_eq_single a (fun b _ hb => False.elim (hb (Subsingleton.elim b a))) (by simp)
  have h1 : mass (coarsen f (update p l))=1 :=
    (coarsen_mass f _).trans (posterior_mass p l (positive_evidence p l hp hl).ne')
  have h2 := posterior_mass (coarsen f p) k
    (positive_evidence _ k (coarsen_probability f p hp) hk).ne'
  exact (hs _).symm.trans (h1.trans (h2.symm.trans (hs _)))
```

The adjacent tower criterion includes this singleton alternative. Composition then gives exact commutation over a finite span of varying state spaces.

4.4 The coarsest meaningful partition

`BayesianPartitions` forms a quotient by equality of the whole likelihood profile. Its canonical coarse likelihood recovers each fine likelihood. Under strict positivity, every nontrivial all-prior-closed partition refines the profile partition: the canonical profile map factors uniquely through the given partition map:

Source: KomorebiPaperVI/BayesianPartitions.lean.

```
theorem canonical_coarsest_nontrivial (l : Y → I → ℝ) (hl : ∀ y i, 0 < l y i)
    (f : I → A) (hf : Function.Surjective f) [Nontrivial A] (h : FamilyCloses l f) :
    ∃! u : A → Packet l, ∀ i, u (f i)=packetMap l i :=
  canonical_unique_factor l f hf ((all_prior_family_iff_resolves l hl f hf).mp h)
```

The qualifier “nontrivial” excludes the automatic one-packet case. The theorem does not claim that every family has a nontrivial canonical quotient: a separate declaration supplies nontriviality when two profiles differ. A broader statistical sufficiency statement requires its own statistical model and hypotheses.

4.5 Information loss is a specific matrix

The formal information-loss matrix is $\mathrm{diag}(P) - bP^{\top}$, where P is coarse prior mass and b is the coarse posterior. It acts on the mismatch between the effective and prescribed coarse likelihoods. The exact factorization is:

Source: KomorebiPaperVI/InformationLoss.lean.

```
theorem information_loss_matrix (f : I → A) (p l : I → ℝ) (k : A → ℝ)
    (hp : ∀ i, 0 ≤ p i) (hz : evidence p l ≠ 0)
    (hk : evidence (coarsen f p) k ≠ 0) (a : A) :
    coarsen f (update p l) a-update (coarsen f p) k a =
      (lossMatrix (coarsen f p) (update (coarsen f p) k)).mulVec
```

```
      (fun j => effective f p l j-k j) a/evidence p l := by
  rw [effective_factorization f p l hp, lossMatrix_apply]
  have he := posterior_difference (coarsen f p) (effective f p l) k
    (by rwa [effective_evidence f p l hp]) hk a
  simpa only [effective_evidence f p l hp] using he
```

The scale direction is in its nullspace because multiplying a likelihood by a nonzero scalar does not change its normalized posterior. The norm estimate then combines this factorization with the likelihood perturbation bound. This is the matrix-valued defect used in core 8.4. Relative-entropy chain rules in Part II are different claims and are not implied by the shared word "information."

4.6 A normalized exponential flow

For a score function g, $p_i(t)$ is proportional to $p_i(0)e^{tg_i}$. The source establishes positive evidence, simplex preservation, the additive-time law, and the centered multiplicative derivative:

Source: `KomorebiPaperVI/BayesianFlow.lean`.

```
theorem flow_derivative (p g : I → ℝ) (hp : IsProbability p) (t : ℝ) (i : I) :
    HasDerivAt (fun u => flow p g u i)
      ((g i-(∑ j, g j*flow p g t j))*flow p g t i) t := by
  have hz := (positive_evidence p g hp t).ne'
  have hd := ((likelihood_derivative g t i).mul_const (p i)).div
    (evidence_derivative p g t) hz
  convert! hd using 1
  simp only [flow, update]
  simp only [← mul_div_assoc, ← Finset.sum_div]
  field_simp
```

The derivative contains the posterior mean score. It is therefore nonlinear in the probability vector even though unnormalized multiplication is linear. The additional covariance, cumulant, concentration, and filter stability results retained in the mathematical text have separate scope rows in Section 10.

5 Fractional calculus and refinement towers

5.1 Two constructions with different starting data

`SpectralPackets` starts with a supplied finite spectral resolution. Its finite sums give multiplication, packet reduction, and the actual exponential. It does not silently prove a spectral decomposition for every operator. The additive-exponent law explicitly allows zero eigenvalues while requiring positive exponents:

Source: `KomorebiPaperVI/SpectralPackets.lean`.

```
theorem fractional_add (P : I → R) (h : ∀ i j, P i*P j=if i=j then P i else 0)
    (lam : I → ℝ) (hl : ∀ i, 0 ≤ lam i) (a b : ℝ) (ha : 0 < a) (hb : 0 < b) :
    fractional P lam a*fractional P lam b=fractional P lam (a+b) := by
  unfold fractional
  rw [resolve_mul P h]
  congr 1
  funext i
  exact (Real.rpow_add' (hl i) (add_pos ha hb).ne').symm
```

The bounded Hilbert-space refinement result uses continuous functional calculus and a normalized Bochner resolvent integral. This is a different route and has a broader operator domain than a finite spectral list. The ledger records the exact setting for each result.

5.2 Poisson subordination includes the integral

The square-root transfer is recovered from the heat transfer using the normalized Poisson kernel. `ReciprocalGaussian` proves the scalar integral, `PoissonKernel` supplies integrability, and `PoissonSubordination` transports the scalar identities across a finite spectral sum. Its endpoint asserts both integrability and equality with the actual exponential:

Source: `KomorebiPaperVI/PoissonSubordination.lean`.

```
theorem operator_subordination (P : I → R) (hP : ∑ i,P i=1)
    (h : ∀ i j,P i*P j=if i=j then P i else 0) (lam : I → ℝ)
    (hl : ∀ i,0 ≤ lam i) (t : ℝ) (ht : 0 < t) :
    IntegrableOn (fun s => kernel t s • NormedSpace.exp ((-s) • resolve P lam)) (Ioi 0) ∧
    NormedSpace.exp ((-t) • fractional P lam (1/2))=
      ∫ s in Ioi 0,kernel t s • NormedSpace.exp ((-s) • resolve P lam) := by
  simp only [operator_integrand P hP h lam]
  refine ⟨finite_spectral_integrable P lam hl t ht,?_⟩
  rw [finite_spectral_subordination P lam hl t ht,spectral_transfer_exponential P hP h]
  simp only [spectralTransfer,resolve,Real.sqrt_eq_rpow]
```

The integral formula is stated for $t > 0$. The semigroup value at $t = 0$ is obtained separately from the exponential definition. Nonnegative spectral values include zero. General stable-subordinator statements for arbitrary fractional exponents in Part II are not new endpoints of this square-root formal theorem.

5.3 The normalization constant is proved

For $0 < \alpha < 1$, the resolvent representation uses $\sin(\pi\alpha)/\pi$. `BetaNormalization` derives the scalar integrals and constants. In particular, the common-gap integral evaluates exactly to $\alpha m^{\alpha-1}$ when $m > 0$:

Source: `KomorebiPaperVI/BetaNormalization.lean`.

```
theorem normalized_gap_integral (p m : ℝ) (hp : p∈Ioo 0 1) (hm : 0 < m) :
    (Real.sin (Real.pi*p)/Real.pi)*(∫ t in Ioi 0,t^p/(t+m)^2)=p*m^(p-1) := by
  rw [gap_integral p m hp hm]
  have hs : Real.sin (Real.pi*p) ≠ 0 := by
    intro hs
    have h := sine_factor_positive p hp
    rw [hs,zero_div] at h
    exact (lt_irrefl 0) h
  field_simp
```

This identity supplies the sharp constant in the displayed common-gap certificate. It is not left as an unnamed positive normalization factor.

5.4 The rectangular resolvent defect

The spaces E and F in `RectangularFractional` are complete complex Hilbert spaces. A and B are bounded nonnegative self-adjoint operators in the operator order, and $C : E \to F$ is bounded. Put

$$D = CA - BC, \qquad D_\alpha = CA^\alpha - B^\alpha C.$$

The theorem records the actual inverse-valued integrand and its Bochner integrability:

Source: `KomorebiPaperVI/RectangularFractional.lean`.

```
theorem literal_resolvent_integral (p : ℝ≥0) (hp : (p:ℝ)∈Ioo 0 1)
    (A : E →L[ℂ] E) (B : F →L[ℂ] F) (C : E →L[ℂ] F) (hA : 0 ≤ A) (hB : 0 ≤ B) :
    let f := fun t : ℝ => t^(p:ℝ) • (Ring.inverse (algebraMap ℝ (F →L[ℂ] F) t+B)).comp
      ((defect A B C).comp (Ring.inverse (algebraMap ℝ (E →L[ℂ] E) t+A)))
    IntegrableOn f (Ioi 0) ∧ fractionalDefect A B C p=coefficient p • ∫ t in Ioi 0,f t := by
  dsimp only
  have he : (fun t : ℝ => t^(p:ℝ) • (Ring.inverse (algebraMap ℝ (F →L[ℂ] F) t+B)).comp
      ((defect A B C).comp (Ring.inverse (algebraMap ℝ (E →L[ℂ] E) t+A))))
      =ᵐ[volume.restrict (Ioi 0)] integrand A B C p := by
    filter_upwards [ae_restrict_mem measurableSet_Ioi] with t ht
    rw [literal_integrand p t hp ht A B C hA hB,
      PositiveResolvent.resolvent_inverse A hA t ht,PositiveResolvent.resolvent_inverse B hB t ht]
  have h := normalized_integral p hp A B C hA hB
  exact (h.1.congr he.symm,h.2.trans (congrArg (coefficient p • ·) (integral_congr_ae he.symm)))
```

The sign matches the convention $D = CA - BC$. In this formula the resolvents are $(tI + B)^{-1}$ and $(tI + A)^{-1}$, and the order of the sandwich is fixed by the rectangular domain and codomain.

5.5 A gap-free estimate and a common-gap estimate

The gap-free estimate combines low- and high-parameter bounds on the same integrand. A split at the appropriate scale gives a Hölder estimate with the explicit constant defined in `FractionalNormBounds.holderConstant`. The source handles $C = 0$ and $D = 0$ before dividing by their norms.

Source: `KomorebiPaperVI/RectangularFractional.lean`.

```
theorem holder_estimate (p : ℝ≥0) (hp : (p:ℝ)∈Ioo 0 1)
    (A : E →L[ℂ] E) (B : F →L[ℂ] F) (C : E →L[ℂ] F) (hA : 0 ≤ A) (hB : 0 ≤ B) :
    ‖fractionalDefect A B C p‖ ≤
      FractionalNormBounds.holderConstant p*‖C‖^(1-(p:ℝ))*‖defect A B C‖^(p:ℝ) := by
  by_cases hc : C=0
  · subst C
    simp [fractionalDefect,defect,Real.zero_rpow hp.1.ne']
  by_cases hd : defect A B C=0
  · have he := exact_fractional_intertwining p hp A B C hA hB hd
    rw [he,norm_zero,hd]
    simp [Real.zero_rpow hp.1.ne']
  have hcn : 0 < ‖C‖ := norm_pos_iff.mpr hc
  have hdn : 0 < ‖defect A B C‖ := norm_pos_iff.mpr hd
  have hf := normalized_integral p hp A B C hA hB
  have hk : 0 < coefficient p := BetaNormalization.sine_factor_positive p hp
  have hbound := FractionalScalarBounds.split_norm_bound (integrand A B C p) p (2*‖C‖) ‖defect A B
   ↪  C‖
    (‖defect A B C‖/(2*‖C‖)) hp (by positivity) hf.1
    (fun t ht => low_bound p t hp ht A B C hA hB)
    (fun t ht => high_bound p t ht hp A B C hA hB)
  rw [FractionalScalarBounds.optimize_split p (2*‖C‖) ‖defect A B C‖ hp (by positivity) hdn] at
   ↪  hbound
  rw [hf.2,norm_smul,Real.norm_of_nonneg hk.le]
  calc
    _ ≤ coefficient p*((2*‖C‖)^(1-(p:ℝ))*‖defect A B C‖^(p:ℝ)/((p:ℝ)*(1-(p:ℝ)))) :=
      mul_le_mul_of_nonneg_left hbound hk.le
    _ = _ := by
      rw [Real.mul_rpow (by norm_num : (0:ℝ) ≤ 2) (norm_nonneg C)]
      unfold FractionalNormBounds.holderConstant
      ring
```

With a common lower spectral bound $mI \le A, B$ and $m > 0$, the endpoint is linear in the original defect:

Source: `KomorebiPaperVI/RectangularFractional.lean`.

```
theorem common_gap_estimate (p : ℝ≥0) (hp : (p:ℝ)∈Ioo 0 1) (m : ℝ) (hm : 0 < m)
    (A : E →L[ℂ] E) (B : F →L[ℂ] F) (C : E →L[ℂ] F) (hA : 0 ≤ A) (hB : 0 ≤ B)
    (hgA : algebraMap ℝ (E →L[ℂ] E) m ≤ A) (hgB : algebraMap ℝ (F →L[ℂ] F) m ≤ B) :
    ‖fractionalDefect A B C p‖ ≤ (p:ℝ)*m^((p:ℝ)-1)*‖defect A B C‖ := by
  have hd := normalized_integral p hp A B C hA hB
  have hk : 0 < coefficient p := BetaNormalization.sine_factor_positive p hp
  have hs : 0 < Real.sin (Real.pi*(p:ℝ)) := by

      ring
```

Real finite-matrix applications use the ordinary complexification specialization disclosed in the inherited review. The project does not count that manual specialization as a separately formalized construction.

5.6 The sign in fractional evolution

Fractional evolution is $e^{-tA^{\alpha}}$. Its Duhamel formula has a minus sign relative to the e^{tA} convention. Combining decay with the common-gap estimate yields the final generator-level bound:

Source: `KomorebiPaperVI/RectangularSemigroup.lean`.

```
theorem generator_gap_bound (A : E →L[ℂ] E) (B : F →L[ℂ] F) (C : E →L[ℂ] F)
    (hA : 0 ≤ A) (hB : 0 ≤ B) (p : ℝ≥0) (hp : (p:ℝ)∈Ioo 0 1) (t m : ℝ) (ht : 0 ≤ t) (hm : 0 < m)
    (hgA : algebraMap ℝ (E →L[ℂ] E) m ≤ A) (hgB : algebraMap ℝ (F →L[ℂ] F) m ≤ B) :
    ‖timeDefect A B C p t‖ ≤ t*Real.exp (-t*m^(p:ℝ))*(p:ℝ)*m^((p:ℝ)-1)*‖defect A B C‖ := by
  calc
    _ ≤ t*Real.exp (-t*m^(p:ℝ))*‖fractionalDefect A B C p‖ :=
      fractional_gap_bound A B C hA hB p hp.1 t m ht hm.le hgA hgB
    _ ≤ t*Real.exp (-t*m^(p:ℝ))*((p:ℝ)*m^((p:ℝ)-1)*‖defect A B C‖) :=
      mul_le_mul_of_nonneg_left (common_gap_estimate p hp m hm A B C hA hB hgA hgB) (by
       ↪  positivity)
    _ = _ := by ring
```

The bound vanishes when the generator defect vanishes. It assumes nonnegative time and the same positive common gap as the fractional power estimate. It does not establish norm convergence for arbitrary unbounded generators.

5.7 What is summed across varying spaces

In `RectangularTowers`, H_n may vary with n, and $C_n : H_{n+1} \to H_n$. The individual defects therefore lie in different operator spaces. The formal series is a series of *real norms*. The endpoint says its partial sums converge uniformly on bounded nonnegative time intervals:

Source: `KomorebiPaperVI/RectangularTowers.lean`.

```
theorem bounded_time_uniform_convergence (A : ∀ n,H n →L[ℂ] H n) (C : ∀ n,H (n+1) →L[ℂ] H n)
    (hA : ∀ n,0 ≤ A n) (p : ℝ≥0) (hp : 0 < p) (T : ℝ)
    (hs : Summable (fractionalNorm A C p)) :
    TendstoUniformlyOn (fun N t => ∑ n ∈ Finset.range N,timeNorm A C p t n)
      (fun t => ∑' n,timeNorm A C p t n) Filter.atTop (Icc 0 T) := by
  apply tendstoUniformlyOn_tsum_nat (hs.mul_left T)
  intro n t ht
  rw [Real.norm_of_nonneg (show 0 ≤ timeNorm A C p t n from norm_nonneg _)]
  exact bounded_time_majorant A C hA p hp T t ht n
```

Two sufficient generator criteria precede this theorem: summability of the α-powers of generator-defect norms with uniformly bounded C_n, or ordinary summability with a common positive spectral gap. An inherited fixed-space formulation also proves operator-series convergence. It must not be relabeled as an operator sum across unrelated Hom spaces. A coherent limiting evolution additionally needs the ambient completion and closure hypotheses discussed in the retained written extensions.

6 Green reconstruction and finite paths

6.1 The inverse is the literal inverse

`DiscreteGreen` builds the Dirichlet tridiagonal matrix on `Fin n`. It proves a second-difference identity for the kernel, treats both boundary terms, multiplies the matrix by that kernel, and then identifies the actual nonsingular inverse. The endpoint is short because the preceding multiplication identity carries the main work:

Source: `KomorebiPaperVI/DiscreteGreen.lean`.

```
theorem inverse_eq_kernel (n : ℕ) : (tridiagonal n)⁻¹=inverseKernel n := by
  exact Matrix.inv_eq_right_inv (tridiagonal_inverse_kernel n)
```

For $h = 1/(n+1)$ and $L_h = h^{-2}\,\mathrm{tridiag}(-1, 2, -1)$, the precise scaling is

$$h^{-1}(L_h^{-1})_{ij} = G(x_i, x_j), \qquad G(x, y) = \min(x, y) - xy.$$

The formal statement uses zero-based `Fin n` indices and adds one to obtain the interior nodes:

Source: `KomorebiPaperVI/DiscreteGreen.lean`.

```
theorem grid_reconstruction (n : ℕ) (i j : Fin n) :
    ((n:ℝ)+1)*(laplacian n)⁻¹ i j=
      min (((i.val:ℝ)+1)/((n:ℝ)+1)) (((j.val:ℝ)+1)/((n:ℝ)+1))-
        (((i.val:ℝ)+1)/((n:ℝ)+1))*(((j.val:ℝ)+1)/((n:ℝ)+1)) := by
  rw [laplacian_inverse]
  simp only [Matrix.smul_apply,smul_eq_mul,inverseKernel,green,Nat.cast_add,Nat.cast_one]
  rw [min_div_div_right (by positivity)]
  field_simp
```

This is an exact node identity. It is not by itself a uniform convergence theorem for an arbitrary continuous forcing function or a higher-dimensional mesh. Those quadrature and PDE estimates need the separate regularity assumptions stated in the traditional chapter.

6.2 Low modes have an explicit error bound

`LowModeConvergence` proves a scalar sine-square estimate and substitutes it into the discrete eigenvalue formula. It gives

$$0 \le \omega^2 - \frac{4}{h^2}\sin^2\!\left(\frac{\omega h}{2}\right) \le \frac{\omega^4 h^2}{12}, \qquad h \neq 0.$$

The Lean endpoint retains the nonzero-spacing hypothesis:

Source: `KomorebiPaperVI/LowModeConvergence.lean`.

```
theorem low_mode_error (w h : ℝ) (hh : h≠0) :
    0 ≤ w^2-eigenvalue w h ∧ w^2-eigenvalue w h ≤ w^4/12*h^2 := by
  have hs := sine_square_error (w*h/2)
  have hpos : 0 ≤ 4/h^2 := by positivity
  have he : w^2-eigenvalue w h=4/h^2*((w*h/2)^2-Real.sin (w*h/2)^2) := by
```

```
    unfold eigenvalue
    field_simp
    ring
  rw [he]
  constructor
  · exact mul_nonneg hpos hs.1
  · calc
      _ ≤ 4/h^2*((w*h/2)^4/3) := mul_le_mul_of_nonneg_left hs.2 hpos
      _ = w^4/12*h^2 := by field_simp; ring
```

For a fixed low mode, set $\omega = k\pi$ and let positive h tend to zero. The constant depends on that fixed ω. This statement does not make high-frequency error uniform when k grows with mesh resolution.

6.3 Probability columns and observable rows

For the finite path formula, K_{ji} is the transition probability from i to j. An observable f propagates by $K^\top$, and the potential is evaluated at the departure state. Therefore the source transfer is

$$F = \operatorname{diag}(e^{-V})K^\top.$$

Source: KomorebiPaperVI/FeynmanKac.lean.

```
noncomputable def transfer (K : Matrix I I ℝ) (V : I → ℝ) : Matrix I I ℝ :=
  Matrix.diagonal (fun i => Real.exp (-V i))*K.transpose
```

The path law is defined recursively for exactly n steps. At $n = 0$ there is an empty path, path probability one, zero accumulated potential, and the starting state as terminal state. Induction on the path length gives the matrix-power formula:

Source: KomorebiPaperVI/FeynmanKac.lean.

```
theorem feynman_kac_path_formula (K : Matrix I I ℝ) (V f : I → ℝ) (n : ℕ) :
    (transfer K V ^ n).mulVec f=pathExpectation K V f n := by
  induction n with
  | zero => funext i; simp [path_expectation_zero]
  | succ n ih =>
    rw [pow_succ',← Matrix.mulVec_mulVec,ih]
    funext i
    rw [path_expectation_step]
    simp only [Matrix.mulVec,dotProduct,transfer_entry,Finset.mul_sum,mul_assoc]
```

The algebraic equality itself does not require stochastic hypotheses. To call the path weights a probability law, use the separate declarations proving nonnegativity and total mass one from entrywise nonnegative K and unit column sums. Separate product, potential-sum, and terminal-index theorems ensure that the recursive law is the intended finite path expression. The continuous-time Feynman–Kac and product-slicing extensions retained in Parts II and III remain outside this discrete endpoint.

7 Schur elimination and nonnormal memory

7.1 A projected resolvent needs two invertibility facts

For retained and hidden coordinates $P \oplus Q$, the Schur complement is

$$S(z) = zI - A_{PP} - A_{PQ}(zI - A_{QQ})^{-1}A_{QP}.$$

`SchurFeshbach` uses literal complex block matrices. The projected inverse formula assumes invertibility of both the full resolvent matrix and the hidden block:

Source: `KomorebiPaperVI/SchurFeshbach.lean`.

```
theorem projected_resolvent (App : Matrix P P ℂ) (Apq : Matrix P Q ℂ)
    (Aqp : Matrix Q P ℂ) (Aqq : Matrix Q Q ℂ) (z : ℂ)
    [Invertible (Matrix.scalar Q z-Aqq)]
    [Invertible (Matrix.scalar (P ⊕ Q) z-Matrix.fromBlocks App Apq Aqp Aqq)] :
    ((Matrix.scalar (P ⊕ Q) z-Matrix.fromBlocks App Apq Aqp Aqq)⁻¹).submatrix
      Sum.inl Sum.inl = (schur App Apq Aqp Aqq z)⁻¹ := by
  let D := Matrix.scalar Q z-Aqq
  let A := Matrix.scalar P z-App
  have he := resolvent_blocks App Apq Aqp Aqq z
  let : Invertible (Matrix.fromBlocks A (-Apq) (-Aqp) D) := Invertible.copy ‹_› _ he.symm
  let : Invertible (A-(-Apq)*⅟D*(-Aqp)) := Matrix.invertibleOfFromBlocks₂₂Invertible A (-Apq)
   ↪  (-Aqp) D
  have hinv := Matrix.invOf_fromBlocks₂₂_eq A (-Apq) (-Aqp) D
  have hs : A-(-Apq)*⅟D*(-Aqp)=schur App Apq Aqp Aqq z := by
    simp only [Matrix.neg_mul,Matrix.mul_neg,neg_neg,Matrix.invOf_eq_nonsing_inv,schur,D,A]
  rw [he,← Matrix.invOf_eq_nonsing_inv,hinv]
  change ⅟(A-(-Apq)*⅟D*(-Aqp))=(schur App Apq Aqp Aqq z)⁻¹
  rw [Matrix.invOf_eq_nonsing_inv]
  congr 1
```

The module also proves the invertibility equivalence between the full block matrix and its Schur complement when the hidden block is invertible. The retained block is an inverse Schur complement, not simply the resolvent of A_{PP}. The difference is the self-energy $A_{PQ}(zI - A_{QQ})^{-1}A_{QP}$.

7.2 The fifth checked block removes a normality shortcut

The earlier memory layer establishes Laplace inversion from a supplied exponential growth estimate and also treats normal elements. The latest core 13.2 goes further for arbitrary finite complex matrices: a strict spectral half-plane alone yields integrability and decay. Nonnormality can create polynomial factors in time, so the proof must account for nilpotent generalized eigenspace contributions.

The scalar input is integrability of a complex exponential times a polynomial whenever the real part of the exponent is negative:

Source: `KomorebiPaperVI/ScalarDecay.lean`.

```
theorem exp_pow_integrable (a : ℂ) (ha : a.re < 0) (k : ℕ) :
    IntegrableOn (fun t : ℝ => Complex.exp (a*t)*(t:ℂ)^k) (Ioi 0) := by
  have hi := integrableOn_rpow_mul_exp_neg_mul_rpow
```

```
    (s := (k:ℝ)) (p := (1:ℝ)) (b := -a.re) (by linarith [Nat.cast_nonneg (α := ℝ) k]) zero_lt_one
    ↪ (by linarith)
  simp only [Real.rpow_natCast,Real.rpow_one,neg_neg] at hi
  apply hi.mono' (by fun_prop)
  filter_upwards [ae_restrict_mem measurableSet_Ioi] with t ht
  rw [norm_exp_pow a k t ht.le]
```

There is also a separate zero-limit theorem. Neither a numerical quadrature nor an assertion about eigenvalue locations substitutes for these analytic steps.

7.3 From generalized eigenspaces to a finite sum

`NonnormalMemory` studies left multiplication by A on a finite-dimensional complex C^*-algebra. A complex matrix algebra is a specialization. The source decomposes this vector space into generalized eigenspaces. On one component the exponential is a finite polynomial times $e^{\mu t}$:

Source: `KomorebiPaperVI/NonnormalMemory.lean`.

```
theorem exp_mul_component (A : R) (μ : ℂ) (x : R)
    (hx : x ∈ (Module.End.maxGenEigenspace (LinearMap.mulLeft ℂ A)) μ) (t : ℝ) :
    transfer A t*x=Complex.exp (μ*t) •
      ∑ k ∈ Finset.range (finrank ℂ R),((t:ℂ)^k/(k.factorial:ℂ)) • ((A-μ • 1)^k*x) := by
  classical
  let : NormedAlgebra ℚ R := NormedAlgebra.restrictScalars ℚ ℝ R
  let D := A-μ • 1
  have hkill (k : ℕ) (hk : finrank ℂ R ≤ k) : D^k*x=0 := by
    rw [← left_shift_power]
    exact CanonicalJets.power_kills _ μ x hx k hk
  have hs := (exp_series_hasSum_exp' (𝕂 := ℂ) ((t:ℂ) • D)).mul_right x
  have he : exp ((t:ℂ) • D)*x=
      ∑ k ∈ Finset.range (finrank ℂ R),((t:ℂ)^k/(k.factorial:ℂ)) • (D^k*x) := by
    have hs' : HasSum (fun k : ℕ => ((t:ℂ)^k/(k.factorial:ℂ)) • (D^k*x))
        (exp ((t:ℂ) • D)*x) := by
      simpa only [smul_pow,Algebra.smul_mul_assoc,smul_smul,div_eq_mul_inv,mul_comm] using hs
    exact hs'.unique (hasSum_sum_of_ne_finset_zero (fun k hk => by
      rw [hkill k (by simpa using hk),smul_zero]))
  have ht : t • A=algebraMap ℂ R (μ*t)+(t:ℂ) • D := by
    simp only [D,smul_sub,Algebra.algebraMap_eq_smul_one,smul_smul]
    rw [RCLike.real_smul_eq_coe_smul (K := ℂ),mul_comm μ (t:ℂ)]
    abel
  rw [transfer,ht,exp_add_of_commute (Algebra.commutes _ _),
    ← algebraMap_exp_comm,← Complex.exp_eq_exp_ℂ,Algebra.algebraMap_eq_smul_one,
    Algebra.smul_mul_assoc,one_mul,Algebra.smul_mul_assoc,he]
```

The cutoff is the complex dimension of the ambient algebra. For an $n \times n$ matrix algebra that can be n^2. It need not be a minimal Jordan-block length. The proof only needs a valid nilpotence cutoff. Terms beyond that cutoff vanish on the component.

After damping by e^{-zt}, each coefficient has exponent $\mu - z$ with negative real part. The source combines the scalar integrability and limit results over finite sums and then over the generalized-eigenspace decomposition. Applying the resulting identity to the algebra unit gives the operator-valued decay:

Source: KomorebiPaperVI/NonnormalMemory.lean.

```
theorem spectral_decay (A : R) (z : ℂ) (hz : ∀ μ∈spectrum ℂ A,μ.re < z.re) :
    IntegrableOn (damped A z) (Ioi 0) ∧ Tendsto (damped A z) atTop (𝓝 0) := by
  have h (x : R) : IntegrableOn (fun t => damped A z t*x) (Ioi 0) ∧
      Tendsto (fun t => damped A z t*x) atTop (𝓝 0) := by
    apply Submodule.iSup_induction (Module.End.maxGenEigenspace (LinearMap.mulLeft ℂ A))
      (x := x) (motive := fun x => IntegrableOn (fun t : ℝ => damped A z t*x) (Ioi 0) volume ∧
        Tendsto (fun t => damped A z t*x) atTop (𝓝 0))
      (by rw [Module.End.iSup_maxGenEigenspace_eq_top]; trivial)
    · exact component_decay A z hz
    · simp
    · intro x y hx hy
      simpa only [Pi.add_def,mul_add,add_zero] using And.intro (hx.1.add hy.1) (hx.2.add hy.2)
  simpa using h 1
```

The condition is strict: $\operatorname{Re}\mu < \operatorname{Re} z$ for every spectral value. The conclusion includes both Bochner integrability and the limit zero. It does not rely on a claimed universal bound $\|e^{tA}\| \leq e^{t \max \operatorname{Re}\sigma(A)}$, which would fail for general nonnormal matrices.

7.4 Why both derivative identities appear

The improper-integral fundamental theorem is applied once to left multiplication and once to right multiplication. These establish both inverse equations. This is what connects the integral to the actual inverse, rather than just presenting a formal solution to one equation.

Source: KomorebiPaperVI/NonnormalMemory.lean.

```
theorem spectral_laplace_inverse (A : R) (z : ℂ)
    (hz : ∀ μ∈spectrum ℂ A,μ.re < z.re) :
    IntegrableOn (damped A z) (Ioi 0) ∧ IsUnit (algebraMap ℂ R z-A) ∧
      (∫ t in Ioi 0,damped A z t)=Ring.inverse (algebraMap ℂ R z-A) := by
  have hs := spectral_decay A z hz
  let B := A-algebraMap ℂ R z
  have he : damped A z=transfer B := funext (damped_eq_shifted A z)
  rw [he] at hs ⊢
  have hl := integral_Ioi_of_hasDerivAt_of_tendsto'
    (fun t (_ : t∈Ici (0:ℝ)) => transfer_derivative_left B t)
    ((ContinuousLinearMap.mul ℝ R B).integrable_comp hs.1) hs.2
  have hr := integral_Ioi_of_hasDerivAt_of_tendsto'
    (fun t (_ : t∈Ici (0:ℝ)) => transfer_derivative_right B t)
    (((ContinuousLinearMap.mul ℝ R).flip B).integrable_comp hs.1) hs.2
  rw [integral_const_mul_of_integrable hs.1,transfer_zero,zero_sub] at hl
  rw [integral_mul_const_of_integrable hs.1,transfer_zero,zero_sub] at hr
  have hn : algebraMap ℂ R z-A= -B := by dsimp [B]; abel
  have hl' : (algebraMap ℂ R z-A)*(∫ t in Ioi 0,transfer B t)=1 := by
    rw [hn,neg_mul,hl,neg_neg]
  have hr' : (∫ t in Ioi 0,transfer B t)*(algebraMap ℂ R z-A)=1 := by
    rw [hn,mul_neg,hr,neg_neg]
  have hu : IsUnit (algebraMap ℂ R z-A) := ⟨⟨_,_,hl',hr'⟩,rfl⟩
  refine ⟨hs.1,hu,?_⟩
```

```
  calc
    _ = Ring.inverse (algebraMap ℂ R z-A)*((algebraMap ℂ R z-A)*(∫ t in Ioi 0,transfer B t)) :=
      (Ring.inverse_mul_cancel_left _ _ hu).symm
    _ = _ := by rw [hl',mul_one]
```

The result supplies invertibility as part of the conclusion. The total operation `Ring.inverse` is therefore being used at an established unit. This is the formal endpoint connecting the strict spectral half-plane with a genuine resolvent formula.

7.5 Retained and hidden dimensions can differ

The final matrix theorem uses A on hidden coordinates J, $U : J \to I$, and $V : I \to J$. It wraps $B \mapsto UBV$ as a continuous linear map and commutes that map with the Bochner integral. The result is the literal rectangular memory/self-energy identity:

Source: `KomorebiPaperVI/MatrixMemory.lean`.

```
theorem rectangular_memory_self_energy (A : Matrix J J ℂ)
    (U : Matrix I J ℂ) (V : Matrix J I ℂ) (z : ℂ)
    (hz : ∀ μ∈spectrum ℂ A,μ.re < z.re) :
    IntegrableOn (fun t : ℝ => Complex.exp (-z*t) • (U*transfer A t*V)) (Ioi 0) ∧
    (∫ t : ℝ in Ioi 0,Complex.exp (-z*t) • (U*transfer A t*V))=
      U*(Matrix.scalar J z-A)⁻¹*V := by
  have h := NonnormalMemory.spectral_laplace_inverse A z hz
  have he : (fun t : ℝ => Complex.exp (-z*t) • (U*transfer A t*V))=
      (fun t => sandwich U V (damped A z t)) := by
    ext t i j
    simp [sandwich,damped]
  rw [he]
  refine ⟨(sandwich U V).integrable_comp h.1,?_⟩
  rw [(sandwich U V).integral_comp_comm h.1,h.2.2]
  change U*Ring.inverse (algebraMap ℂ (Matrix J J ℂ) z-A)*V=_
  rw [Matrix.nonsing_inv_eq_ringInverse]
  rfl
```

The source imposes no equality of retained and hidden dimensions and no nonemptiness assumption on the finite index types. The theorem includes nilpotent Jordan parts and zero-dimensional cases. It proves a finite-dimensional Laplace identity. General infinite hidden systems, globally optimal model reduction, and arbitrary memory closure remain separate questions.

8 Canonical jets and holomorphic naturality

Core 15.1 closes a common source of ambiguity: what exactly is meant by $f(A)$ when A is a nonnormal finite matrix and f is holomorphic on a possibly disconnected neighborhood of the spectrum? The final layer defines a canonical finite-jet operator, proves uniqueness and intertwining, and identifies its coefficients with genuine local Cauchy integrals under analytic hypotheses.

8.1 The finite-jet definition

For coefficient data $a(\mu, k)$, the jet at μ is a polynomial in $A - \mu I$:

Source: KomorebiPaperVI/CanonicalJets.lean.

```
noncomputable def jet (A : End ℂ V) (a : ℂ → ℕ → ℂ) (μ : ℂ) (n : ℕ) : End ℂ V :=
  ∑ k ∈ Finset.range n, a μ k • (A-μ • 1)^k
```

The canonical operator applies this polynomial on each generalized eigenspace and reassembles the direct sum:

Source: KomorebiPaperVI/CanonicalJets.lean.

```
noncomputable def calculus (A : End ℂ V) (a : ℂ → ℕ → ℂ) : End ℂ V := by
  classical
  exact (DirectSum.toModule ℂ ℂ V (fun μ =>
    (jet A a μ (finrank ℂ V)).comp (A.maxGenEigenspace μ).subtype)).comp
    (DirectSum.decomposeLinearEquiv A.maxGenEigenspace).toLinearMap
```

The decomposition is selected noncomputably, but the resulting operator is characterized uniquely by its action on each component. `HolomorphicFinite.canonical_unique` proves that characterization. "Noncomputable" means the definition uses classical constructions without an executable algorithm. It does not mean the proof is admitted.

8.2 Unequal dimensions require a common cutoff

If $CA = BC$, then C takes a generalized eigenspace of A into the corresponding one of B. Source and target may have different dimensions, so the naturality proof first extends both finite jets to a common maximum cutoff. Truncation stability makes that extension harmless:

Source: KomorebiPaperVI/CanonicalJets.lean.

```
theorem jet_stable (A : End ℂ V) (a : ℂ → ℕ → ℂ) (μ : ℂ) (x : V)
    (hx : x ∈ A.maxGenEigenspace μ) (n : ℕ) (hn : finrank ℂ V ≤ n) :
    jet A a μ n x=jet A a μ (finrank ℂ V) x := by
  classical
  unfold jet
  simp only [LinearMap.sum_apply,LinearMap.smul_apply]
  symm
  apply Finset.sum_subset (Finset.range_mono hn)
  intro k _ hk
  rw [power_kills A μ x hx k (by simpa using hk),smul_zero]
```

The source then applies polynomial intertwining componentwise and uses the direct-sum extensionality principle:

Source: KomorebiPaperVI/CanonicalJets.lean.

```
theorem canonical_naturality (A : End ℂ V) (B : End ℂ W) (C : V →ₗ[ℂ] W)
    (h : B.comp C=C.comp A) (a : ℂ → ℕ → ℂ) :
    C.comp (calculus A a)=(calculus B a).comp C := by
  apply DirectSum.decompose_lhom_ext A.maxGenEigenspace
  intro μ
  ext x
  have hx := Module.End.mapsTo_genEigenspace_of_comp C h μ ⊤ x.property
  change C (calculus A a x)=calculus B a (C x)
  rw [calculus_on_component A a μ x x.property,
    calculus_on_component B a μ (C x) hx,
    ← jet_stable A a μ x x.property (max (finrank ℂ V) (finrank ℂ W)) (le_max_left _ _),
    ← jet_stable B a μ (C x) hx (max (finrank ℂ V) (finrank ℂ W)) (le_max_right _ _)]
  exact jet_intertwines A B C h a μ _ x
```

This is an algebraic theorem about arbitrary coefficient data a. It is already enough to explain why the same local jets must be used on both sides of an intertwining equation.

8.3 Analyticity enters the interpretation

`CanonicalJets.holomorphic` substitutes the derivative coefficients $f^{(k)}(\mu)/k!$. The term exists for any function because Lean's derivative operations are totalized. The raw jet-naturality theorem therefore has no analyticity assumption. That fact must not be mistaken for a theorem that an arbitrary function has an analytic holomorphic functional calculus.

For an analytic f, Cauchy's formula connects the derivative coefficient to an actual positive-radius circle integral:

Source: KomorebiPaperVI/HolomorphicFinite.lean.

```
theorem cauchyCoefficient_eq (f : ℂ → ℂ) (μ : ℂ) (r : ℝ) (hr : 0 < r)
    (hf : DifferentiableOn ℂ f (Metric.closedBall μ r)) (k : ℕ) :
    cauchyCoefficient f μ r k=iteratedDeriv k f μ/(k.factorial:ℂ) := by
  have hh := hf.circleIntegral_one_div_sub_center_pow_smul hr k
  simp only [smul_eq_mul,one_div] at hh
  unfold cauchyCoefficient
  have he : (fun z => f z/(z-μ)^(k+1))=(fun z => ((z-μ)^(k+1))⁻¹*f z) := by
    ext z
    simp [div_eq_mul_inv,mul_comm]
  rw [he,hh]
  field_simp
```

The radius is positive and f is differentiable on the whole closed disk in this statement. A later theorem chooses suitable local disks inside any declared open neighborhood where f is analytic:

Source: KomorebiPaperVI/HolomorphicFinite.lean.

```
theorem canonical_contours_exist (A : End ℂ V) (f : ℂ → ℂ) (U : Set ℂ)
    (hU : IsOpen U) (hf : AnalyticOnNhd ℂ f U) (hA : spectrum ℂ A ⊆ U) :
    ∃ r : ℂ → ℝ,(∀ μ∈spectrum ℂ A,0 < r μ ∧ Metric.closedBall μ (r μ) ⊆ U) ∧
      calculus A (fun μ k => cauchyCoefficient f μ (r μ) k)=holomorphic A f := by
```

```
  classical
  have he (μ : ℂ) : ∃ r : ℝ,0 < r ∧
      (μ∈spectrum ℂ A → Metric.closedBall μ r ⊆ U) := by
    by_cases hm : μ∈spectrum ℂ A
    · obtain ⟨r,hr,hsub,_⟩ := admissible_circle f U hU hf μ (hA hm)
      exact ⟨r,hr,fun _ => hsub⟩
    · exact ⟨1,zero_lt_one,fun h => (hm h).elim⟩
  choose r hr hsub using he
  refine ⟨r,fun μ hμ => ⟨hr μ,hsub μ hμ⟩,?_⟩
  apply canonical_cauchy_representation A f r (fun μ _ => hr μ)
  intro μ hμ z hz
  exact (hf z (hsub μ hμ hz)).differentiableAt.differentiableWithinAt
```

The local radius can depend on the spectral value. This supports disconnected analytic neighborhoods and avoids assuming a single globally convergent Taylor series. Equality of the Cauchy coefficients proves independence of the admissible local circles. General contour deformation in arbitrary Banach algebras is not the formal scope of this finite-dimensional construction.

8.4 The final literal matrix equation

`matrixFunction` transfers the finite-jet operator from linear maps back to matrices. The resulting equation is rectangular and uses the original matrix intertwining hypothesis:

Source: `KomorebiPaperVI/HolomorphicFinite.lean`.

```
theorem matrix_holomorphic_naturality (A : Matrix I I ℂ) (B : Matrix J J ℂ)
    (C : Matrix J I ℂ) (h : C*A=B*C) (f : ℂ → ℂ) :
    C*matrixFunction A f=matrixFunction B f*C := by
  have hh : B.toLin'.comp C.toLin'=C.toLin'.comp A.toLin' := by
    rw [← Matrix.toLin'_mul,← Matrix.toLin'_mul,h]
  have hc := holomorphic_naturality A.toLin' B.toLin' C.toLin' hh f
  have hm := congrArg LinearMap.toMatrix' hc
  simpa only [LinearMap.toMatrix'_comp,LinearMap.toMatrix'_toLin',matrixFunction] using hm
```

Read this as naturality of the defined jet operator for arbitrary f, and as ordinary finite-dimensional holomorphic naturality when the preceding analytic hypotheses identify those jets with the desired holomorphic calculus. The bounded Banach reciprocal-family substitution moved from Chapter IV has a broader setting and retains its own written proof in Part III. It has not acquired a new Lean endpoint by being moved into Chapter VI.

9 Survival, hazard, and incomplete absorption

`Survival` begins with a finite real matrix whose off-diagonal entries are nonnegative and whose column sums are nonpositive. Its exponential evolves the surviving transient-state mass. With a nonnegative initial probability vector, survival is positive at every finite nonnegative time, the density is nonnegative, and survival is decreasing.

9.1 Finite-time positivity makes the hazard meaningful

The source proves strict positivity of $S(t)$, rather than treating $h(t) = f(t)/S(t)$ as legitimate by notation alone. Integrating the logarithmic derivative then yields the hazard identity:

Source: `KomorebiPaperVI/Survival.lean`.

```
theorem survival_hazard (A : Matrix I I ℝ) (hA : ∀ i j, i≠j → 0 ≤ A i j)
    (p : I → ℝ) (hp : ∀ i,0 ≤ p i) (hs : ∑ i,p i=1) (t : ℝ) (ht : 0 ≤ t) :
    survival A p t=Real.exp (-∫ r in 0..t,hazard A p r) := by
  have hd : ∀ r∈Icc 0 t, HasDerivAt (fun u => Real.log (survival A p u)) (-hazard A p r) r := by
    intro r hr
    simpa [hazard,neg_div] using (survival_derivative A p r).log
      (survival_positive A hA p hp hs r hr.1).ne'
  have hscont : Continuous (survival A p) :=
    (show Differentiable ℝ (survival A p) from fun r => (survival_derivative A p
    ↪  r).differentiableAt).continuous
  have hhcont : ContinuousOn (hazard A p) (Icc 0 t) :=
    (density_continuous A p).continuousOn.div hscont.continuousOn
      (fun r hr => (survival_positive A hA p hp hs r hr.1).ne')
  have hi := intervalIntegral.integral_eq_sub_of_hasDerivAt
    (by simpa [uIcc_of_le ht] using hd)
    (hhcont.neg.intervalIntegrable_of_Icc ht)
  simp only [Pi.neg_apply,intervalIntegral.integral_neg,survival_zero,hs,Real.log_one,sub_zero] at
  ↪  hi
  rw [hi,Real.exp_log (survival_positive A hA p hp hs t ht)]
```

The displayed theorem's hypotheses establish the relevant finite-time positivity and normalization. The nonpositive-column-sum condition is used in the density and monotonicity results. Keep these neighboring statements together when interpreting a model as a killed Markov evolution.

9.2 A density need not integrate to one

A finite subgenerator can leave positive surviving mass as $t \to \infty$. The formal result therefore proves existence of a limit and integrates the density to $1 - \ell$, not automatically to one:

Source: `KomorebiPaperVI/Survival.lean`.

```
theorem defective_density_mass (A : Matrix I I ℝ) (hA : ∀ i j, i≠j → 0 ≤ A i j)
    (hc : ∀ j,∑ i,A i j ≤ 0) (p : I → ℝ) (hp : ∀ i,0 ≤ p i) (hs : ∑ i,p i=1) :
    ∃ l,0 ≤ l ∧ Tendsto (survival A p) atTop (𝓝 l) ∧
      IntegrableOn (density A p) (Ioi 0) ∧ (∫ t in Ioi 0,density A p t)=1-l := by
  obtain ⟨l,hl,ht⟩ := survival_has_limit A hA hc p hp
  have hd := fun t (_ : t∈Ici (0:ℝ)) => survival_derivative A p t
```

```
have hn := fun t (ht : t∈Ioi (0:ℝ)) =>
  neg_nonpos.mpr (density_nonnegative A hA hc p hp t ht.le)
have hi := integrableOn_Ioi_deriv_of_nonpos' hd hn ht
have he := integral_Ioi_of_hasDerivAt_of_nonpos' hd hn ht
refine ⟨l,hl,ht,integrable_neg_iff.mp hi,?_⟩
simp only [integral_neg,survival_zero,hs] at he
linarith
```

The separate `eventual_absorption_density` endpoint assumes $S(t) \to 0$ and then obtains a unit-mass density. This distinction is essential in a phase-type application: eventual absorption is a hypothesis to establish, not an effect of calling a matrix transient in prose. Transform, moment, residual-life, and competing-risk formulas in the retained extensions have additional assumptions and are mapped separately.

10 The retained extensions and the formal boundary

The mathematical text contains more mathematics than the 33-result kernel ledger. A nearby formal identity can explain an extension's architecture without proving that extension. This section maps the regions by mathematical content. "Related core" is a navigation aid, not a certificate for the entire row.

10.1 Part II: the strengthened branch

The labels in this table use Part II's E prefix. The 84 theorem-like result records in that branch retain their written proofs. The precise hypotheses are stated in the mathematical text.
The table does not enlarge the formal denominator.

Written region	Related core	Formal boundary
E2: packet semigroups	1.2, 2.1, 2.2	Formal actual exponential and finite packet convolution. General C_0 semigroups, Dyson expansions, and packet-path resolvent series require their retained written assumptions.
E3: generator defects	3.1–3.3, 15.1	Rectangular Duhamel and matrix resolvent endpoints are formal. General Banach holomorphic defect formulas exceed finite canonical-jet naturality.
E4: limiting refinement	10.5	Formal varying-space norm summability does not construct every inverse-limit semigroup. Weighted completion, range leakage, generator closure, and limiting state-space choices are separate written results.
E5: Markov lumping	4.1, 5.1, 5.2	Exponential probability preservation and exact/approximate iterates are formal. Quotient obstructions, complete descent characterizations, and stationary descent have separate written proofs.
E6: conditional towers	6.1, 6.2	Finite weighted kernels and difference packets are formal. General conditional expectation and every expanded variance identity are not additional ledger endpoints.
E7: Gaussian/Hermite	None directly	The Ornstein–Uhlenbeck semigroup, infinite Hermite reconstruction, generator, Dirichlet form, spectral gap, and fractional Hermite transfer are outside this formal core.
E8: Bayesian transfer	7.1–7.3	Composition, evidence packets, and likelihood perturbation are formal. Prior-stability statements require their own exact interface and are not counted by analogy.
E9: finite sufficiency	8.1, 8.2, 8.4–8.6	Effective likelihoods, all-prior criteria, coarsest nontrivial partitions, and the loss matrix are formal within the ledger scope. Relative-entropy decomposition and data processing are separate written results.
E10: Bayesian flows/HMM	9.1, 9.3	The normalized exponential flow and one-step simplex preservation are formal. Cumulants, concentration, and quantitative filtering bounds are retained written extensions.
E11: fractional operators	10.1–10.5	Actual normalized integrals, rectangular bounded Hilbert-space defects, and square-root subordination are formal. General stable-subordinator exposition is not a new formal endpoint.

Written region	Related core	Formal boundary
E12: Green/PDE	11.1, 11.2	Exact finite Dirichlet inverse, grid-node identity, and scalar low-mode error are formal. Quadrature, forcing-error, and broader mode-transfer estimates retain their stated regularity assumptions.
E13: Feynman–Kac	12.1	The exact discrete finite path law is formal. Continuous-time probabilistic representation and product slicing have separate written proofs.
E14: Schur elimination	13.1, 13.2	Actual block inverse and finite-dimensional Laplace memory identity are formal. The full time-domain closure criterion is not separately included in the ledger.
E15: memory compression	13.2	The finite nonnormal exponential-polynomial mechanism is formal. Certified block selection, realizations, compression optimization, and Volterra trajectory bounds are written extensions.
E16: survival/risks	14.1	Finite survival, hazard, and defective density mass are formal. Transform moments, residual-life descriptions, and competing-risk decompositions have separate written scope.

10.2 Part III: earlier results retained in their own right

The earlier Annals branch contains results whose scope or constants are not fully subsumed by the strengthened text. Their retained statements and proofs appear in Part III, with R-prefixed numbering. The accompanying navigation crosswalk lists every retained theorem-like record and its final traditional location. Retention preserves the mathematics. It does not create new Lean declarations.

These results include multilevel telescoping and coordinate-generator arguments, reversible descent and Dirichlet forms, prior-relative Bayesian sufficiency, quantitative normalization and information-loss estimates, covariance and hidden-Markov formulas, potential perturbation and coarse Feynman–Kac transfer, and finite rational memory or phase-type descriptions. Each has to be compared against a formal theorem by its exact hypotheses and conclusion. Shared vocabulary is insufficient.

10.3 The operator substitution migrated from Chapter IV

The migrated reciprocal-family proposition concerns bounded Banach operators and holomorphic functional calculus, together with an explicit classical functional-calculus input. It belongs with Chapter VI's operator language and is retained with its written proof. The core 15.1 result instead constructs and proves naturality of canonical finite-dimensional jets. Their relationship is conceptual. The migrated proposition is outside the 33-result formal contract.

10.4 The three original continuum conjectures

The formal core retains three open conjectures: transfer-semigroup realization on completed state spaces; uniform refinement control for meaningful discretization families; and latent-packet closure for stable infinite packet systems. Finite or bounded special cases proved elsewhere in this book do not settle these universal formulations. In particular, summable local defects alone do not guarantee a semigroup limit without the appropriate completion, compatibility, and closure conditions.

10.5 Traditional chapter navigation

The Printed and PDF columns locate results in the attached Chapter VI source document. Printed labels and physical PDF pages differ because of the opening material. These locations refer to that source document rather than the continuous folios of this book.

Core	Result	Printed	PDF
1.2	Finite semigroup law	3	10
2.1	Packet semigroup convolution	4	11
2.2	Reducing packets	4	11
3.1	Exact Duhamel refinement identity	5	12
3.2	Norm bound	6	13
3.3	Resolvent refinement identity	6	13
4.1	Finite Markov semigroup	7	14
5.1	Exact lumpability	8	15
5.2	Finite-horizon defect formula	8	15
6.1	Finite conditional-expectation projector	9	16
6.2	Tower law and martingale packets	10	17
7.1	Independent-likelihood composition	11	18
7.2	Bayesian packet reconstruction	11	18
7.3	Likelihood perturbation bound	12	19
8.1	Exact effective-likelihood factorization	13	20
8.2	Bayesian refinement criterion	14	21
8.4	Bayesian information-loss packet	14	21
8.5	Nested Bayesian packet tower	15	22
8.6	Canonical coarsest likelihood-resolving partition	15	22
9.1	Bayesian nonlinear semigroup	18	25
9.3	Prediction-update reconstruction	19	26
10.1	Fractional packet calculus	20	27
10.2	Poisson subordination	21	28
10.3	Fractional intertwining theorem	22	29
10.4	Fractional semigroup refinement	23	30
10.5	Fractional refinement towers	23	30
11.1	Exact discrete Green reconstruction at grid nodes	25	32
11.2	Second-order low-mode convergence	25	32
12.1	Discrete Feynman–Kac path formula	27	34
13.1	Schur–Feshbach projected resolvent	28	35
13.2	Memory/self-energy correspondence	29	36
14.1	Semigroup survival identities	30	37
15.1	Naturality under exact intertwining	32	39

The 24 earlier results retained in Part III. These have written proofs. This list creates no additional Lean completion claim.

The migrated bounded Banach reciprocal proposition is R7.2, printed page 101 (PDF page 108). Its scope remains outside the 33-result contract.

11.5 Building this reading guide

From the directory for the editable Lean guide, run `python3 build.py`. It compiles the supplied TeX and excerpt files with XeLaTeX and does not invoke Lean or regenerate mathematical evidence. The build uses installed URW P052 and Nimbus Sans, Latin Modern mono and math, and DejaVu Sans Mono fonts. Font files are resolved locally with `kpsewhich` and standard system locations, then copied only into the private build stage. No font binaries are bundled or downloaded. The monograph style is supplied beside the TeX source. The script copies the full authored guide tree to a temporary directory and compiles it in four passes. No installation is performed. `verify_pdf.py` performs the documented PDF checks and renders all pages into contact sheets.

`assemble.py` is a separate step for generating documentation. It reads the preserved source snapshot, exact source contract, selected excerpt list, and a current verification report. Its default inputs are relative to the supplied package. It also accepts `--source` and `--verification` paths when those inputs are stored elsewhere. Its generated tables are already supplied for ordinary PDF reproduction. Run `python3 reconcile_sources.py` to check those tables and excerpts against the preserved sources without changing their mathematical content.

11.6 When a reuse needs a new proof

Before adapting an endpoint, check the scalar field, finite versus bounded setting, positivity notion, time domain, evidence condition, and domain/codomain of every operator. Changing a hypothesis is not a formatting edit. A new theorem about unbounded generators, general statistical sufficiency, infinite hidden-state elimination, or unrestricted Banach holomorphic calculus requires its own proof and correspondence review. The preserved project supplies a precise starting point for that work.

12 Complete ledger of the 33 scoped results

This ledger reproduces the recorded checked scope from `THEOREM_LEDGER.json`. Numbering refers to the latest core in Part I of the traditional chapter. These are 33 manuscript result records, not 33 source declarations and not a certification of every retained extension. The declaration catalog in Section 13 resolves every named target to its module and original line.

12.1 1.2 / Finite semigroup law

Recorded status. Complete scoped statement in the formal-core correspondence.

Real Banach-algebra exponential law and both derivatives; finite operators are a specialization.

Declared targets.

- `KomorebiPaperVI.Semigroups.transfer_add`. Source line 20.
- `KomorebiPaperVI.Semigroups.transfer_zero`. Source line 18.
- `KomorebiPaperVI.Semigroups.transfer_derivative_left`. Source line 29.
- `KomorebiPaperVI.Semigroups.transfer_derivative_right`. Source line 26.

12.2 2.1 / Packet semigroup convolution

Recorded status. Complete scoped statement in the formal-core correspondence.

Actual exponential packet convolution for a finite idempotent resolution of identity.

Declared targets.

- `KomorebiPaperVI.Algebra.block_reconstruction`. Source line 12.
- `KomorebiPaperVI.Semigroups.exponential_packet_convolution`. Source line 44.

12.3 2.2 / Reducing packets

Recorded status. Complete scoped statement in the formal-core correspondence.

A finite orthogonal idempotent resolution with zero off-diagonal generator blocks commutes with the generator; actual exponential cross blocks vanish and compressed dynamics agree with the exponential of the compressed generator.

Declared targets.

- `KomorebiPaperVI.ReducingPackets.generator_commutes`. Source line 12.
- `KomorebiPaperVI.ReducingPackets.reducing_exponential`. Source line 32.
- `KomorebiPaperVI.ReducingPackets.compressed_evolution`. Source line 39.

12.4 3.1 / Exact Duhamel refinement identity

Recorded status. Complete scoped statement in the formal-core correspondence.

Bochner interval-integral identity for rectangular bounded real operators on Banach spaces, and exact intertwining.

Declared targets.

- `KomorebiPaperVI.Semigroups.duhamel_integrand_derivative`. Source line 57.

- `KomorebiPaperVI.Semigroups.duhamel_rectangular`. Source line 70.
- `KomorebiPaperVI.Semigroups.exact_rectangular_intertwining`. Source line 81.

12.5 3.2 / Norm bound

Recorded status. Complete scoped statement in the formal-core correspondence.

The displayed exponential-growth integral estimate for rectangular bounded real operators, with the contraction specialization.

Declared targets.

- `KomorebiPaperVI.OperatorBounds.growth_duhamel_bound`. Source line 10.
- `KomorebiPaperVI.Semigroups.contraction_duhamel_bound`. Source line 89.

12.6 3.3 / Resolvent refinement identity

Recorded status. Complete scoped statement in the formal-core correspondence.

Literal rectangular matrices with left/right inverse equations and central scalar; applies to the stated resolvents.

Declared targets.

- `KomorebiPaperVI.Algebra.rectangular_resolvent_identity`. Source line 85.

12.7 4.1 / Finite Markov semigroup

Recorded status. Complete scoped statement in the formal-core correspondence.

The actual real matrix exponential of any finite generator has nonnegative entries and columns summing to one for nonnegative time; consequently it preserves probability vectors.

Declared targets.

- `KomorebiPaperVI.MarkovSemigroup.markov_nonnegative`. Source line 48.
- `KomorebiPaperVI.MarkovSemigroup.markov_column_sum`. Source line 71.
- `KomorebiPaperVI.MarkovSemigroup.markov_probability`. Source line 84.

12.8 5.1 / Exact lumpability

Recorded status. Complete scoped statement in the formal-core correspondence.

Literal rectangular matrix intertwining for every natural-number iterate.

Declared targets.

- `KomorebiPaperVI.Algebra.intertwining_powers`. Source line 53.

12.9 5.2 / Finite-horizon defect formula

Recorded status. Complete scoped statement in the formal-core correspondence.

The literal rectangular finite-sum defect identity and the norm bound for arbitrary rectangular contractions, including horizon zero and zero spaces.

Declared targets.

- `KomorebiPaperVI.Algebra.finite_horizon_defect`. Source line 64.
- `KomorebiPaperVI.OperatorBounds.finite_horizon_contraction`. Source line 50.

12.10 6.1 / Finite conditional-expectation projector

Recorded status. Complete scoped statement in the formal-core correspondence.

Literal finite complex weighted conditional expectation: idempotence, self-adjointness for the weighted inner product, and range exactly the block-constant functions. Strictly positive finite weights are explicit.

Declared targets.

- `KomorebiPaperVI.ConditionalExpectation.expect_idempotent`. Source line 49.
- `KomorebiPaperVI.ConditionalExpectation.expect_self_adjoint`. Source line 105.
- `KomorebiPaperVI.ConditionalExpectation.expect_range`. Source line 74.
- `KomorebiPaperVI.ConditionalExpectation.expect_matrix`. Source line 84.

12.11 6.2 / Tower law and martingale packets

Recorded status. Complete scoped statement in the formal-core correspondence.

Both concrete conditional-expectation tower identities; arbitrary pairs of nested projector kernels multiply to the coarser kernel; their differences are pairwise orthogonal idempotents and sum to the terminal projector.

Declared targets.

- `KomorebiPaperVI.ConditionalTowers.conditional_kernel_product`. Source line 37.
- `KomorebiPaperVI.ConditionalTowers.nested_kernel_min`. Source line 53.
- `KomorebiPaperVI.ConditionalTowers.martingale_packet_product`. Source line 65.
- `KomorebiPaperVI.ConditionalTowers.martingale_packet_reconstruction`. Source line 72.

12.12 7.1 / Independent-likelihood composition

Recorded status. Complete scoped statement in the formal-core correspondence.

Composition with explicit nonzero first and combined evidences; positive evidences imply these hypotheses.

Declared targets.

- `KomorebiPaperVI.FiniteBayes.sequential_evidence`. Source line 37.
- `KomorebiPaperVI.FiniteBayes.posterior_composition`. Source line 45.

12.13 7.2 / Bayesian packet reconstruction

Recorded status. Complete scoped statement in the formal-core correspondence.

Literal finite fibers and evidence-weighted reconstruction, including zero-evidence packets; specialize nonnegative weights to likelihood times prior.

Declared targets.

- `KomorebiPaperVI.Coarsening.packet_reconstruction_point`. Source line 90.
- `KomorebiPaperVI.Coarsening.packet_reconstruction`. Source line 99.
- `KomorebiPaperVI.Coarsening.zero_packet_component`. Source line 48.

12.14 7.3 / Likelihood perturbation bound

Recorded status. Complete scoped statement in the formal-core correspondence.

The printed finite weighted L1 perturbation bound under nonnegativity and positive evidence.

Declared targets.

- `KomorebiPaperVI.FiniteBayes.normalized_l1_bound_left`. Source line 73.
- `KomorebiPaperVI.FiniteBayes.likelihood_perturbation_bound`. Source line 102.

12.15 8.1 / Exact effective-likelihood factorization

Recorded status. Complete scoped statement in the formal-core correspondence.

Literal finite coarsening and prior-dependent effective likelihood, including zero prior-mass fibers.

Declared targets.

- `KomorebiPaperVI.Coarsening.effective_weight`. Source line 66.
- `KomorebiPaperVI.Coarsening.effective_evidence`. Source line 78.
- `KomorebiPaperVI.Coarsening.effective_factorization`. Source line 83.

12.16 8.2 / Bayesian refinement criterion

Recorded status. Complete scoped statement in the formal-core correspondence.

The all-prior equivalence for strictly positive fine and coarse likelihoods and a surjective partition with at least two packets; necessity is derived from actual two-state priors. Singleton coarsening is automatic.

Declared targets.

- `KomorebiPaperVI.BayesianNecessity.refinement_iff`. Source line 112.
- `KomorebiPaperVI.BayesianNecessity.cross_packet_ratio`. Source line 67.
- `KomorebiPaperVI.BayesianTowers.singleton_commutes`. Source line 30.

12.17 8.4 / Bayesian information-loss packet

Recorded status. Complete scoped statement in the formal-core correspondence.

The literal information-loss matrix factorization, null scale direction, minimum-evidence L1 estimate, and the final fine-to-coarse weighted bound, including zero prior-mass fibers.

Declared targets.

- `KomorebiPaperVI.InformationLoss.information_loss_matrix`. Source line 17.
- `KomorebiPaperVI.InformationLoss.information_loss_null`. Source line 28.
- `KomorebiPaperVI.InformationLoss.information_loss_norm`. Source line 68.
- `KomorebiPaperVI.InformationLoss.total_loss_bound`. Source line 60.
- `KomorebiPaperVI.FiniteBayes.likelihood_perturbation_bound`. Source line 102.

12.18 8.5 / Nested Bayesian packet tower

Recorded status. Complete scoped statement in the formal-core correspondence.

The necessary-and-sufficient adjacent likelihood criterion with singleton exception, and exact Bayesian commutation over every finite span of a varying-state-space tower.

Declared targets.

- `KomorebiPaperVI.BayesianTowers.adjacent_criterion`. Source line 43.
- `KomorebiPaperVI.BayesianTowers.tower_criterion`. Source line 80.
- `KomorebiPaperVI.BayesianTowers.tower_commutes`. Source line 73.
- `KomorebiPaperVI.BayesianTowers.coarsen_comp`. Source line 12.

12.19 8.6 / Canonical coarsest likelihood-resolving partition

Recorded status. Complete scoped statement in the formal-core correspondence.

Actual quotient by equality of likelihood profiles, canonical coarse likelihoods and exact closure, unique factorization from every likelihood-resolving partition, and the corrected coarsest nontrivial all-prior-closed property under strict positivity and distinct profiles.

Declared targets.

- `KomorebiPaperVI.BayesianPartitions.packet_eq_iff`. Source line 28.
- `KomorebiPaperVI.BayesianPartitions.canonical_coarsening`. Source line 38.
- `KomorebiPaperVI.BayesianPartitions.canonical_unique_factor`. Source line 46.
- `KomorebiPaperVI.BayesianPartitions.all_prior_family_iff_resolves`. Source line 67.
- `KomorebiPaperVI.BayesianPartitions.canonical_coarsest_nontrivial`. Source line 85.
- `KomorebiPaperVI.BayesianPartitions.canonical_nontrivial`. Source line 91.

12.20 9.1 / Bayesian nonlinear semigroup

Recorded status. Complete scoped statement in the formal-core correspondence.

Actual normalized real exponential flow on the finite probability simplex, its semigroup law, and centered multiplicative derivative.

Declared targets.

- `KomorebiPaperVI.BayesianFlow.positive_evidence`. Source line 13.
- `KomorebiPaperVI.BayesianFlow.flow_probability`. Source line 25.
- `KomorebiPaperVI.BayesianFlow.flow_add`. Source line 36.
- `KomorebiPaperVI.BayesianFlow.flow_zero`. Source line 45.
- `KomorebiPaperVI.BayesianFlow.flow_derivative`. Source line 64.

12.21 9.3 / Prediction-update reconstruction

Recorded status. Complete scoped statement in the formal-core correspondence.

Literal column-stochastic matrix prediction followed by a nonnegative positive-evidence Bayesian update.

Declared targets.

- `KomorebiPaperVI.FiniteBayes.prediction_probability`. Source line 124.
- `KomorebiPaperVI.FiniteBayes.prediction_update_probability`. Source line 135.

12.22 10.1 / Fractional packet calculus

Recorded status. Complete scoped statement in the formal-core correspondence.

Fractional powers and transfer for the given finite spectral resolution, including zero eigenvalues; multiplication/addition laws, packet reduction, and identification with the actual algebra exponential. Finite spectral resolution is the stated starting data.

Declared targets.

- `KomorebiPaperVI.SpectralPackets.fractional_add`. Source line 58.
- `KomorebiPaperVI.SpectralPackets.spectral_transfer_exponential`. Source line 68.
- `KomorebiPaperVI.SpectralPackets.spectral_transfer_add`. Source line 77.
- `KomorebiPaperVI.SpectralPackets.fractional_reduces`. Source line 89.
- `KomorebiPaperVI.SpectralPackets.spectral_transfer_reduces`. Source line 96.

12.23 10.2 / Poisson subordination

Recorded status. Complete scoped statement in the formal-core correspondence.

The actual normalized improper Poisson integral for every nonnegative eigenvalue, including zero; Bochner integrability and equality with the actual exponential of the finite spectral square root.

Declared targets.

- `KomorebiPaperVI.PoissonKernel.kernel_mass`. Source line 35.
- `KomorebiPaperVI.PoissonKernel.heat_integrand_integrable`. Source line 54.
- `KomorebiPaperVI.ReciprocalGaussian.reciprocal_square_gaussian`. Source line 127.

- `KomorebiPaperVI.PoissonSubordination.scalar_subordination`. Source line 42.
- `KomorebiPaperVI.PoissonSubordination.finite_spectral_subordination`. Source line 52.
- `KomorebiPaperVI.PoissonSubordination.operator_subordination`. Source line 74.

12.24 10.3 / Fractional intertwining theorem

Recorded status. Complete scoped statement in the formal-core correspondence.

Actual normalized Lebesgue/Bochner resolvent-defect integral for bounded nonnegative self-adjoint operators between distinct complex Hilbert spaces, the exact Holder constant, the alpha*m^(alpha-1) common-gap estimate, and exact fractional intertwining. Real finite matrices use their standard complexification; this ordinary specialization is manually reviewed.

Declared targets.

- `KomorebiPaperVI.BetaNormalization.normalizer_exact`. Source line 80.

12.25 10.4 / Fractional semigroup refinement

Recorded status. Complete scoped statement in the formal-core correspondence.

Actual fractional exponentials between distinct complex Hilbert spaces, rectangular Duhamel identity, contraction estimate, and the final common-gap bound in terms of the original generator defect.

Declared targets.

- `KomorebiPaperVI.RectangularSemigroup.evolution_exponential`. Source line 19.
- `KomorebiPaperVI.RectangularSemigroup.contraction`. Source line 30.
- `KomorebiPaperVI.RectangularSemigroup.gap_decay`. Source line 35.

- `KomorebiPaperVI.RectangularSemigroup.generator_gap_bound`. Source line 94.

12.26 10.5 / Fractional refinement towers

Recorded status. Complete scoped statement in the formal-core correspondence.

Varying complex Hilbert-space towers: both printed generator criteria imply summability of fractional-defect norms and time-defect norms, with uniform convergence of the real norm series on bounded nonnegative time intervals. Operator-series convergence is additionally proved in the inherited fixed-space formulation; no sum across unrelated operator spaces is asserted.

Declared targets.

- `KomorebiPaperVI.RectangularTowers.generator_holder_summable`. Source line 40.
- `KomorebiPaperVI.RectangularTowers.generator_gap_summable`. Source line 49.

12.27 11.1 / Exact discrete Green reconstruction at grid nodes

Recorded status. Complete scoped statement in the formal-core correspondence.

The literal finite Dirichlet tridiagonal matrix, its actual inverse, the scaled discrete Laplacian inverse, and the exact grid-node continuum Green identity for h=1/(n+1).

Declared targets.

- `KomorebiPaperVI.DiscreteGreen.green_second_difference`. Source line 22.
- `KomorebiPaperVI.DiscreteGreen.tridiagonal_inverse_kernel`. Source line 85.
- `KomorebiPaperVI.DiscreteGreen.inverse_eq_kernel`. Source line 109.

- `KomorebiPaperVI.DiscreteGreen.grid_reconstruction`. Source line 122.

12.28 11.2 / Second-order low-mode convergence

Recorded status. Complete scoped statement in the formal-core correspondence.

The exact bound 0 <= w^2 - 4/h^2 sin(w*h/2)^2 <= w^4*h^2/12 for every nonzero spacing, with w=k*pi. This uniform bound implies the printed O(h^2) assertion as positive h tends to zero.

Declared targets.

- `KomorebiPaperVI.LowModeConvergence.sine_square_error`. Source line 8.
- `KomorebiPaperVI.LowModeConvergence.low_mode_error`. Source line 25.

12.29 12.1 / Discrete Feynman–Kac path formula

Recorded status. Complete scoped statement in the formal-core correspondence.

The actual potential-weighted matrix power equals the expectation over all finite paths; the path law is nonnegative and has total mass one for column-stochastic K. Product transition probabilities, the sum over departure-state potentials, and the terminal-state index are proved explicitly.

Declared targets.

- `KomorebiPaperVI.FeynmanKac.path_probability_nonnegative`. Source line 41.
- `KomorebiPaperVI.FeynmanKac.path_probability_mass`. Source line 48.

12.30 13.1 / Schur–Feshbach projected resolvent

Recorded status. Complete scoped statement in the formal-core correspondence.

Literal finite complex block matrices: under invertibility of the full resolvent matrix and the hidden resolvent block, the retained block of the actual inverse is the inverse Schur complement; invertibility equivalence is included.

Declared targets.

- `KomorebiPaperVI.SchurFeshbach.resolvent_blocks`. Source line 14.
- `KomorebiPaperVI.SchurFeshbach.projected_resolvent`. Source line 21.
- `KomorebiPaperVI.SchurFeshbach.schur_invertible`. Source line 40.

12.31 13.2 / Memory/self-energy correspondence

Recorded status. Complete scoped statement in the formal-core correspondence.

For arbitrary finite complex matrices, including nonnormal matrices and nilpotent Jordan parts, the strict spectral half-plane implies actual Bochner integrability and decay of the complex-damped exponential. Both inverse identities are derived by the improper-integral fundamental theorem. The literal rectangular retained/hidden memory integral equals U*(zI-A)^(-1)*V, with the actual matrix inverse and no supplied growth bound.

Declared targets.

- `KomorebiPaperVI.ScalarDecay.exp_pow_integrable`. Source line 16.

- `KomorebiPaperVI.MatrixMemory.rectangular_memory_self_energy`. Source line 19.

12.32 14.1 / Semigroup survival identities

Recorded status. Complete scoped statement in the formal-core correspondence.

Actual finite Metzler-subgenerator exponential: survival derivative and strict positivity at finite nonnegative time, monotonicity, integrated hazard, existence of the survival limit, total defective density mass 1 minus that limit, and the eventual-absorption specialization.

Declared targets.

- `KomorebiPaperVI.Survival.survival_derivative`. Source line 54.
- `KomorebiPaperVI.Survival.survival_positive`. Source line 30.
- `KomorebiPaperVI.Survival.survival_antitone`. Source line 69.

- `KomorebiPaperVI.Survival.defective_density_mass`. Source line 115.
- `KomorebiPaperVI.Survival.eventual_absorption_density`. Source line 129.

12.33 15.1 / Naturality under exact intertwining

Recorded status. Complete scoped statement in the formal-core correspondence.

Canonical basis-free finite Taylor-jet functional calculus on generalized eigenspaces, with uniqueness, truncation stability, dependence only on spectral jets, admissible local Cauchy circles in every declared open holomorphic neighborhood, and independence of those circles. Exact naturality holds for literal rectangular complex matrices without assuming a contour representation or one globally convergent Taylor series. The paper now states this standard finite-dimensional definition explicitly; real matrices are treated by the previously disclosed ordinary complexification specialization.

Declared targets.

- `KomorebiPaperVI.CanonicalJets.calculus_on_component`. Source line 28.

13 All 341 supporting theorem declarations

The inventory is generated from the saved source contract. “Support” means the declaration is included in the audited target inventory but is not named directly as an endpoint in the 33-row manuscript ledger. It can still support a ledger endpoint. This is not a proof-dependency computation. Source lines refer to the immutable production files, not the display excerpts in this guide.

Quantum Seeds and Effective Dynamics

The formal companion to Chapter VII explains the declared hypotheses, theorem correspondences and evidence boundaries.

IN THIS COMPANION

Formal companion 2055

Return to Chapter VII

How to use this volume

A guide to the actual formal development. The formal development covers 19 finite items through 323 named theorem declarations in 25 proof modules. The teaching chapters explain the mathematical interfaces and their hypotheses. The complete registers then give exact declarations, source locations, imports, and nine dependency pins. This guide preserves 67 exact Lean excerpts. Six constructed objects have a separate inherited audit of their proof fields. Those six objects are recorded separately from the catalog of 323 theorems. Five continuum physics conjectures remain open. Kernel execution evidence comes from the recorded formal core build for nineteen results. The guide identifies the source files, declaration locations, saved axiom records and printed excerpts. Finite computations are documented in the reproduction section. This reading guide does not claim a new kernel execution.

1 Reading a Lean theorem from Chapter VII

1.1 Three readings of one construction

The traditional reading begins with a finite state space, its operator algebra and a packet resolution. It derives matrix identities and explains what they mean for dynamics and recovery. The visual reading displays the same objects as corners, address sets, syndrome subspaces and local coordinates. The Lean reading asks a further question: what precise data must be supplied before each conclusion can be constructed?

An endpoint is a theorem whose conclusion expresses the desired result. A supporting lemma may isolate one algebraic or analytic step. A definition constructs an object but is not itself a proof that the object has every advertised property. The formalization deliberately uses several layers: general ring identities, complex matrix specializations, norm estimates, real calculus, spectral constructions and manifold calculus. Reading only a final theorem name loses the distinction between these layers.

The formal source distinguishes three constructions that should not be conflated. Orthogonal syndrome data permit direct recovery. General positive Gram data require spectral reduction and a necessity proof. The range-bundle construction supplies local charts and global manifold curvature. This guide follows the resulting declarations and makes their differing assumptions explicit.

1.2 Finite types, matrix types and type classes

Lean's `Matrix d m ℂ` means a function with a row index in `d`, a column index in `m`, and values in the complex numbers. The indices are types, not necessarily integers. A `Fintype d` instance gives the finite enumeration needed for a sum or dimension. A `DecidableEq d` instance lets a definition decide whether two indices agree. `Fin n` is the type of natural numbers smaller than `n`. It supplies a concrete index type without replacing an arbitrary finite type throughout the library.

The notation `Type*` leaves a universe level implicit. Braces in a binder, such as `{n : Type*}`, denote an implicit argument inferred from later data. Round parentheses denote an explicit argument. Square brackets denote an argument supplied through a type class. This is a structure or property that instance search should obtain. These brackets do not make an assumption disappear. A theorem with `[Nonempty n]` is only available when the state index has an inhabitant. A theorem with `[Invertible D]` has an actual invertibility requirement even though no ordinary parameter named `hD` is printed.

The declarations set `autoImplicit false`. Consequently an undeclared symbol is not silently promoted to a fresh theorem variable. A local `variable` command can still supply variables and type classes to subsequent declarations. An excerpt must therefore be read together with its surrounding section, not as an independent file. The chapter contracts explain those surrounding assumptions. The source file and line register allow the reader to check them directly.

Source notation	Mathematical reading
`Matrix d m ℂ`	This is a rectangular complex matrix. It can also represent the coefficient array of a bipartite state.
`n → ℂ`	This is a coordinate vector on a finite index type.
`→ₗ[ℂ]`	This map is linear over the complex numbers, with linearity stored in its structure.
`→L[ℝ]`	This continuous map is linear over the real numbers. It is used for derivatives and operators that vary with a parameter.
`≃ₗ[ℂ]`	This is a linear equivalence with an inverse and linearity laws.

Source notation	Mathematical reading
`≃ₜ`	This is a homeomorphism, including continuity in both directions.
`≃L[ℝ]`	This is a continuous equivalence that is linear over the real numbers.
`star`, `conjTranspose`	These denote the involution in an abstract star ring and the conjugate transpose for complex matrices.
`PosSemidef`, `PosDef`	These predicates describe positive semidefinite and positive definite matrices, respectively.
`IsStarProjection P`	This predicate requires both idempotence and self-adjointness of the projector.
`HasDerivAt f D t`	The actual real derivative of `f` at `t` is `D`.
`fderiv ℝ`, `mvfderiv I`	These are the Fréchet derivative and the derivative of a map from a manifold to a vector space.
`IsLeast S r`	This asserts that `r` belongs to `S` and is a lower bound for it.

1.3 Quantifiers and the information a structure stores

A family `P : I → R` is one element of the ring for each packet index. A dependent family `P : (i : F) → J i → Matrix (D i) (D i) ℂ` allows both the local dimension and the type of local packet addresses to vary with the tensor factor. This is more general than a tensor power of one fixed matrix.

The packet structure stores pairwise multiplication and completeness. Its multiplication law includes the diagonal case, so idempotence is a consequence. Self-adjointness is supplied separately when the construction is specialized to a star ring. This distinction lets circuit reconstruction work over any ring while the unitary identities require an adjoint.

Source: `formalization/QuantumPacketCore.lean`.

Exact lines 22 to 25. Excerpt `packet_structure`. Hash in Section 12.

```
structure PacketFamily (R I : Type*) [Ring R] [Fintype I] [DecidableEq I] where
  proj : I → R
  mul_proj : ∀ i j, proj i * proj j = if i = j then proj i else 0
  sum_proj : ∑ i, proj i = 1
```

Read `proj : I → R` as the object, `mul_proj` as its orthogonality law and `sum_proj` as its complete resolution of the identity. In a matrix realization the first law is $P_i P_j = \delta_{ij} P_i$. The second is $\sum_i P_i = 1$. No commutative multiplication assumption is present: matrix multiplication remains operator composition.

Structures used later have a different role. `OrthogonalSyndromes` stores an already normalized orthogonal error family, and `KnillLaflamme.Data` stores a general positive Gram matrix. `Data.diagonal` constructs diagonal error data. Its active positive directions are then normalized to construct `OrthogonalSyndromes`. Sufficiency assumes the existence of the general Gram data. Necessity constructs such data from a recovery. The final equivalence joins both directions. The correct reading keeps these roles separate rather than interpreting every structure field as a fact proved from scratch.

1.4 How to read a proof script

The scripts repeatedly use a small set of proof moves. `rw` replaces an expression using a stated equality. `simp only` performs a controlled reduction with an explicit list of lemmas. The broader `simp` tactic also uses the available simplification database. `ext i j` reduces a matrix equality to equality of each entry. `funext` proves equality of functions by comparing values. `constructor` starts the two obligations of a conjunction or equivalence. `rintro` decomposes quantified and existential data. `obtain` names an existential witness already proved to exist. `refine` fixes the overall shape of a term and leaves specified holes to prove.

The tactic `noncomm_ring` normalizes ring expressions without commuting factors. It is appropriate for identities involving $P_b U P_a$. Ordinary `ring` is used for scalar arithmetic or commutative coefficient expressions. A normalization step must therefore be read in the ring where it is used. It does not permit arbitrary matrix factors to be reordered.

A line beginning `have` proves or names a local intermediate assertion. The goal remains the same until that assertion is used. A `calc` block presents a chain of equalities or inequalities. Each link is a separate obligation. Induction on a list proves all finite circuit depths, including the empty list. A finite example verified by `norm_num` or `fin_cases` proves that concrete example, not a theorem in arbitrary dimension.

For a derivative identity, `HasDerivAt.unique` often supplies the final step: two proven derivatives of the same function at a point must coincide. The script first differentiates a product, then rewrites the product as a constant or as a known function, then invokes uniqueness. Thus the differentiated projector and unitary identities are derived from actual functions and their derivatives, rather than postulated as unrelated data of first order.

1.5 Scope is a part of the theorem

The finite results have broad mathematical scope, but their hypotheses also place clear limits on their use. A statement about the span of an algebra orbit permits every matrix in that algebra. Reachability under a physically specified set of unitary gates requires a separate argument. A theorem establishing complete positivity for finite channels quantifies over every finite reference index. Arbitrary infinite reference Hilbert spaces lie outside those declarations. A derivative computation under supplied smoothness does not prove the existence of a Schrödinger solution for every initial condition.

The modules for the projected connection do use arbitrary smooth real parameter manifolds and complete normed model spaces, which is broader than a single finite-dimensional chart. This generality of the mathematical parameter space is distinct from the paper's unproved continuum physics conjectures. Neither the word "manifold" nor an estimate in an abstract C-star algebra supplies a continuum tower, a physical constraint algebra, a renormalized limit or a Lorentzian emergence theorem.

Read each conclusion under its actual hypotheses and use its source locator to recover the surrounding assumptions. Source identity and excerpt fidelity are current documentation checks. Saved compiler and axiom transcripts are inherited proof evidence. This distinction continues through the replay chapter and full result map.

2 Navigation through the traditional paper

The Printed and PDF columns locate results in the attached Chapter VII source document. Physical PDF pages include its cover and opening material. These locations refer to that source document rather than the continuous folios of this book. A shared subject does not imply identical formal coverage.

2.1 All 19 finite items in the traditional core

Item	Number	Core statement	Printed	PDF
2.1	I.2.1	Orbit dimension of one quantum seed	5	13
2.2	I.2.2	Quantum seed-rank formula	5	13

2.2 Strengthened statements and their formal counterparts

This index includes all 79 named statements with proofs in strengthened Part II. A relation identifies shared ingredients or a shared finite result. It does not claim that the whole stronger statement has a dedicated Lean theorem. Entries without a corresponding named endpoint remain written mathematical statements. The formal ledger still contains 19 items, and the declaration inventory still contains 323 entries.

Number (page)	Strengthened statement	Relation to the current formal source	PDF
II.2.2 (36)	Orbit dimension of one seed	Item 2.1 gives the same orbit dimension result.	44
II.2.3 (36)	Quantum seed rank	Item 2.2 gives the same sharp minimum number of seeds.	44
II.2.4 (36)	Local orbit and Schmidt rank	Item 2.3 relates the local orbit to reduced support.	44
II.2.5 (37)	Computational address orbit	Item 2.4 constructs the basis by addressed local X gates.	45

Number (page)	Strengthened statement	Relation to the current formal source	PDF
II.3.1 (38)	Finite group isotypic projectors	The traditional statement has no corresponding named endpoint among the current 25 modules.	46
II.3.2 (38)	Representation matrix units	The traditional statement has no corresponding named endpoint among the current 25 modules.	46
II.3.3 (39)	Cyclic charge projectors	Item 3.1 formalizes the cyclic specialization.	47
II.3.5 (39)	Charge selection rule	The traditional statement has no corresponding named endpoint among the current 25 modules.	47
II.3.6 (39)	Charge addition	The traditional statement has no corresponding named endpoint among the current 25 modules.	47
II.3.7 (40)	Tensor charge refinement	Item 3.2 formalizes finite grouping of tensor packets.	48
II.3.8 (40)	Tensor selection rule	The traditional statement has no corresponding named endpoint among the current 25 modules.	48
II.4.1 (41)	Exact circuit path expansion	Item 4.1 covers every finite circuit depth.	49
II.4.2 (41)	Packet unitarity identities	Item 4.2 gives both operator unitarity identities.	49
II.4.3 (41)	Probability conservation from one packet	Item 4.2 gives the operator identity. The probability corollary is proved in the traditional text.	49
II.4.4 (42)	Path interference formula	The traditional statement has no corresponding named endpoint among the current 25 modules.	50
II.4.5 (42)	Charge pruning of circuit paths	The traditional statement has no corresponding named endpoint among the current 25 modules.	50
II.5.1 (43)	Exact invariant packets	Item 5.1 proves packet invariance for the exponential of a fixed generator.	51
II.5.2 (43)	Off diagonal norm	The traditional statement has no corresponding named endpoint among the current 25 modules.	51
II.5.3 (44)	Fixed packet leakage	Item 5.2 gives the commutator leakage bound. The norm equality for the off-diagonal corner is proved in the traditional text.	52
II.5.4 (44)	Leakage probability	The traditional statement has no corresponding named endpoint among the current 25 modules.	52
II.6.1 (45)	Canonical packet connection	Item 6.3 gives the canonical connection identities along a curve.	53
II.6.2 (45)	Exact Kato transport	The traditional statement has no corresponding named endpoint among the current 25 modules.	53
II.6.3 (46)	Moving frame Hamiltonian	Item 6.1 proves the differentiated equation in moving coordinates.	54
II.6.4 (46)	Moving packet leakage	The traditional statement has no corresponding named endpoint among the current 25 modules.	54

II.6.5 (47)	Direct packet rotation	The traditional statement has no corresponding named endpoint among the current 25 modules.	55
II.6.6 (47)	Convergence of short packet rotations	The traditional statement has no corresponding named endpoint among the current 25 modules.	55
II.6.7 (49)	Nonabelian packet connection	Item 6.4 gives projected manifold curvature and gauge gluing. The local formulas in orthonormal frames are proved in the traditional text.	57
II.6.8 (49)	Bloch sphere curvature	The traditional statement has no corresponding named endpoint among the current 25 modules.	57
II.7.2 (50)	Complete operator packet system	The traditional statement has no corresponding named endpoint among the current 25 modules.	58
II.7.4 (50)	Dephasing as conditional expectation	The traditional statement has no corresponding named endpoint among the current 25 modules.	58
II.7.5 (51)	Block diagonal measurement invariance	Item 7.1 proves trace invariance for block diagonal observables.	59
II.7.6 (52)	Exact channel block calculus	The traditional statement has no corresponding named endpoint among the current 25 modules.	60
II.7.8 (53)	Coherence order projectors	The traditional statement has no corresponding named endpoint among the current 25 modules.	61
II.7.9 (53)	Covariant channels preserve coherence order	The traditional statement has no corresponding named endpoint among the current 25 modules.	61
II.7.10 (53)	Choi symmetry criterion	The traditional statement has no corresponding named endpoint among the current 25 modules.	61
II.7.11 (54)	Choi packet decomposition	The traditional statement has no corresponding named endpoint among the current 25 modules.	62
II.7.14 (55)	Charge preservation by a Lindblad generator	The traditional statement has no corresponding named endpoint among the current 25 modules.	63
II.7.15 (55)	Independent coherence evolution	The traditional statement has no corresponding named endpoint among the current 25 modules.	63
II.8.2 (56)	Knill Laflamme as obstruction vanishing	Item 8.1 gives the criterion for unnormalized error families and recovery on their span. The traditional text also uses a quotient formulation.	64
II.8.3 (57)	Orthogonal syndrome construction	Item 8.1 reduces general positive Gram data by spectral diagonalization.	65
II.8.4 (57)	Exact recovery on the error span	Item 8.1 uses one total recovery for normalized channels in the error span.	65

Number (page)	Strengthened statement	Relation to the current formal source	PDF
II.8.5 (58)	Syndrome measurement preserves logical information	The identities for syndrome cross errors support item 8.1. The traditional text supplies the measurement interpretation.	66
II.8.7 (58)	Meaning of the approximate defect	The traditional statement has no corresponding named endpoint among the current 25 modules.	66
II.9.2 (60)	Exact projected resolvent	Item 9.1 gives the projected resolvent with both required invertibility hypotheses.	68
II.9.3 (60)	Spectral equivalence	Item 9.1 relates invertibility of the full matrix and its Schur complement. The traditional text adds spectral and eigenvector formulations.	68
II.9.4 (61)	Upper half plane sign	The traditional statement has no corresponding named endpoint among the current 25 modules.	69
II.9.5 (61)	Uniform self energy bounds	The traditional statement has no corresponding named endpoint among the current 25 modules.	69
II.9.6 (62)	Low energy expansion	The traditional statement has no corresponding named endpoint among the current 25 modules.	70
II.9.7 (62)	Bare truncation error identity	The traditional statement has no corresponding named endpoint among the current 25 modules.	70
II.9.8 (63)	Exact retained memory equation	The traditional statement has no corresponding named endpoint among the current 25 modules.	71
II.9.9 (63)	Positive definite quantum memory	The traditional statement has no corresponding named endpoint among the current 25 modules.	71
II.9.10 (63)	Finite oscillatory memory expansion	The traditional statement has no corresponding named endpoint among the current 25 modules.	71
II.9.11 (64)	Exact local closure criterion	The traditional statement has no corresponding named endpoint among the current 25 modules.	72
II.9.12 (65)	Stability of the self energy	The traditional statement has no corresponding named endpoint among the current 25 modules.	73
II.9.13 (65)	Uniform Feshbach control	The traditional statement has no corresponding named endpoint among the current 25 modules.	73
II.10.1 (66)	Finite Euclidean transfer	Item 10.1 constructs the shifted exponential and proves its positivity and spectral bounds under the stated hypotheses.	74
II.10.2 (66)	Hamiltonian reconstruction from transfer	The traditional statement has no corresponding named endpoint among the current 25 modules.	74
II.10.3 (66)	Finite reflection positivity	The traditional statement has no corresponding named endpoint among the current 25 modules.	74

II.13.7 (77)	Constraint closure under norm convergence	The traditional statement has no corresponding named endpoint among the current 25 modules.	85
II.13.8 (77)	Heat trace convergence from trace norm	The traditional statement has no corresponding named endpoint among the current 25 modules.	85

2.3 Retained supplements explain the constructed proofs

Part III presents the mathematical content of the six formal supplements. The endpoint map identifies the precise formal coverage of each result and its source. A broader construction is read with its own hypotheses rather than inferred from a restricted special case.

Sections	Retained proof material	Printed	PDF
III.1–III.5	This supplement develops packet algebra, symmetry and measurements. It states the corrected resolvent and spacing hypotheses and audits finite constraints.	81–85	89–93
III.6–III.10	This supplement constructs an addressed computational seed, tensor refinements, moving coordinates, the canonical connection and Kraus amplification.	86–90	94–98
III.11–III.14	This supplement derives orbit spaces and sharp seed counts. It defines Schmidt rank independently and develops cyclic characters and the Euclidean exponential.	91–94	99–102
III.15–III.17	This supplement proves leakage for the exponential, projected curvature in a chart and total recovery from orthogonal syndromes.	95–97	103–105
III.18–III.23	This supplement proves spectral reduction for general Gram data, necessity from recovery, the bridge from states to operators, and correction with finite references and error spans.	98–104	106–112
III.24–III.27	This supplement constructs local products for the range, smooth transitions and the global connection. It proves the gauge law and manifold curvature formula.	104–106	112–114

3 Seeds, local orbits, and the packet resolution

3.1 One seed: identify the actual image before counting it

The starting coefficient array is $C \in \mathrm{Mat}_{d\times m}(\mathbb{C})$. Left multiplication by an arbitrary $d \times d$ matrix changes each row independently within the row space of C. This observation gives the orbit dimension formula. Lean first defines the row space as the range of the linear map given by right multiplication. It then defines the orbit as the range of that map acting on all d rows. The dimension is derived from this construction.

Contract. The row and multiplicity index types `d` and `m` have finite enumerations. The orbit under the algebra action is $\{AC : A \in \mathrm{Mat}_{d\times d}(\mathbb{C})\}$, which is already a linear subspace. The dimension formula permits an empty row type. The equivalence characterizing a full orbit adds `[Nonempty d]` because it cancels the positive row cardinality.

The lemma `mem_orbit_iff_rows` supplies both directions. If $X = AC$, each row of X is a linear combination of rows of C. Conversely, choose one coefficient row for each row of X, collect them into a matrix A, and obtain $AC = X$. The latter choice is an existence argument using classical choice. It is not a numerical algorithm for choosing coefficients.

The explicit linear equivalence below expresses this correspondence for each row. Its domain is the subspace of reachable coefficient arrays. Its codomain is the function space whose value at each row is a member of the row space. Both inverse laws reduce to the underlying functions.

Source: `formalization/SeedOrbit.lean`.

Exact lines 45 to 52. Excerpt `row_equiv`. Hash in Section 12.

```
noncomputable def orbitRowEquiv (C : Matrix d m ℂ) :
    orbitSpace C ≃ₗ[ℂ] (d → rowSpace C) where
  toFun X i := ⟨X.val i, (mem_orbit_iff_rows C X.val).mp X.property i⟩
  invFun f := ⟨fun i => (f i).val, (mem_orbit_iff_rows C _).mpr (fun i => (f i).property)⟩
  left_inv _ := rfl
  right_inv _ := rfl
  map_add' _ _ := rfl
  map_smul' _ _ := rfl
```

Proof reading. The `toFun` field extracts the rows and attaches the proof that each row belongs to the row space. The `invFun` field assembles those rows, using the reverse membership implication. The equalities of functions are definitional, so the inverse and linearity proofs are `rfl`. Taking dimensions of this equivalence gives $|d|$ rank C. The extra `orbit_span` lemma identifies the subspace with the span of the literal action set.

Source: `formalization/SeedOrbit.lean`.

Exact lines 68 to 71. Excerpt `orbit_dimension`. Hash in Section 12.

```
theorem span_orbit_dimension (C : Matrix d m ℂ) :
    finrank ℂ (Submodule.span ℂ (Set.range fun A : Matrix d d ℂ => A * C)) =
      Fintype.card d * C.rank := by
  rw [orbit_span, orbit_dimension]
```

Source: formalization/SeedOrbit.lean.

Exact lines 73 to 80. Excerpt cyclic_rank. Hash in Section 12.

```
theorem cyclic_iff_full_rank [Nonempty d] (C : Matrix d m ℂ) :
    orbitSpace C = ⊤ ↔ C.rank = Fintype.card m := by
  rw [Submodule.eq_top_iff_finrank_eq, orbit_dimension]
  have hdim : finrank ℂ (Matrix d m ℂ) = Fintype.card d * Fintype.card m := by
    change finrank ℂ (d → m → ℂ) = _
    simp [Module.finrank_pi_fintype]
  rw [hdim]
  exact Nat.mul_left_cancel_iff (Fintype.card_pos)
```

The nonempty condition deserves attention. If there are no row indices, the ambient coefficient space is zero and every orbit is already full, regardless of the multiplicity index. Cancelling $|d|$ would be invalid. Lean's final cancellation explicitly uses `Fintype.card_pos`. This records why the test for full rank needs an inhabitant. Multiplicity zero is permitted and gives a target of dimension zero.

3.2 Several seeds: stack them and prove a minimum

Continue with a nonempty row index type. For k seeds C_a, the allowed generation is

$$X = \sum_{a \in k} A_a C_a,$$

where the algebra element A_a may differ for each seed. The question is whether this family generates the whole space linearly. The implementation records its universal quantifier over X and its existential family of coefficient matrices.

Source: formalization/SeedOrbit.lean.

Exact lines 127 to 128. Excerpt seed_generate. Hash in Section 12.

```
def Generates (C : k → Matrix d m ℂ) : Prop :=
  ∀ X : Matrix d m ℂ, ∃ A : k → Matrix d d ℂ, ∑ a, A a * C a = X
```

Source: formalization/SeedOrbit.lean.

Exact lines 148 to 150. Excerpt stack_rank. Hash in Section 12.

```
theorem generates_iff_rank [Nonempty d] (C : k → Matrix d m ℂ) :
    Generates C ↔ (stackSeeds C).rank = Fintype.card m := by
  rw [generates_iff_rowOrbit, rowOrbit_full]
```

Stacking the seeds gives one matrix with row index $k \times d$. Its row space is the span of all the seed rows. The lemma `stacked_action` proves entrywise that multiplication by the large coefficient matrix is exactly the displayed sum. The rank test therefore says that the stacked seed matrix has full column rank. A rank upper bound gives the necessary inequality $|m| \leq |k||d|$.

The reverse direction is constructive at the matrix level. When the number of columns does not exceed the available row slots, choose an injection of column indices into row indices and place a 1 at each corresponding coordinate, with zeros elsewhere. The associated multiplication map is injective because its selected output coordinates reproduce the original input coordinates. The rank theorem follows from that injectivity.

Source: formalization/SeedOrbit.lean.

Exact lines 158 to 171. Excerpt full_column. Hash in Section 12.

```
theorem exists_full_column_rank (h : Fintype.card m ≤ Fintype.card d) :
    ∃ C : Matrix d m ℂ, C.rank = Fintype.card m := by
  classical
  obtain ⟨f⟩ := Function.Embedding.nonempty_of_card_le h
  let C : Matrix d m ℂ := fun i j => if i=f j then 1 else 0
  have hC (x : m → ℂ) (j : m) : (C *ᵥ x) (f j) = x j := by
    simp [C, Matrix.mulVec, dotProduct, f.injective.eq_iff]
  have hi : Function.Injective C.mulVecLin := by
    intro x y hxy
    funext j
    have h := congrFun hxy (f j)
    simpa only [Matrix.mulVecLin_apply, hC] using h
  refine ⟨C, ?_⟩
  rw [Matrix.rank, LinearMap.finrank_range_of_inj hi, Module.finrank_pi]
```

For a finite family of direct summands, dd mm : I → ℕ gives the matrix row dimension and multiplicity of each block. A seed contains one coefficient array in every block. BlockGenerates quantifies over simultaneous block targets and permits simultaneous block algebra elements. The equivalence block_generates_iff proves that this is exactly the collection of individual generation tests. It does not replace the simultaneous problem by an unproved heuristic.

Contract. Every row dimension dd i is positive. Multiplicities mm i may vanish. The block index I is any finite type, including the empty type. The formula is the finite supremum of ceiling divisions in the natural numbers, so an empty block family gives zero.

Define

$$r = \max_{i \in I} \left\lceil \frac{m_i}{d_i} \right\rceil .$$

The source writes this as Finset.univ.sup with natural ceiling division. The lemma seed_formula_le_iff translates $r \leq s$ into all inequalities $m_i \leq s d_i$. The existence equivalence constructs seeds exactly when those inequalities hold. The final result is IsLeast: it proves both that r seeds exist and that every successful seed count is at least r.

Source: formalization/SeedOrbit.lean.

Exact lines 239 to 246. Excerpt seed_minimum. Hash in Section 12.

```
theorem quantum_seed_rank (dd mm : I → ℕ) (hd : ∀ i, 0 < dd i) :
    IsLeast {s : ℕ | ∃ C : Fin s → (i : I) → Matrix (Fin (dd i)) (Fin (mm i)) ℂ,
      BlockGenerates dd mm C} (seedRankFormula dd mm) := by
  constructor
  · exact (exists_block_seeds_iff dd mm hd _).mpr
      ((seed_formula_le_iff dd mm hd _).mp le_rfl)
  · intro s hs
    exact (seed_formula_le_iff dd mm hd s).mpr ((exists_block_seeds_iff dd mm hd s).mp hs)
```

Proof reading. The first half of the pair uses le_rfl to show the formula satisfies its own inequalities, then applies the proved existence criterion. The second half takes any witness at count s, converts its existence to the inequalities, then converts those inequalities back to $r \leq s$. Thus minimality and attainability are both present. The conclusion is stronger than merely displaying a candidate formula.

3.3 Schmidt rank is independently defined

For a bipartite vector $\psi : d \times m \to \mathbb{C}$, `coefficientEquiv` identifies $\psi(i,j)$ with the coefficient matrix C_{ij}. The local action $A \otimes 1$ becomes AC in those standard product coordinates. This identity is proved by expanding the Kronecker product and summing over the product index.

Source: `formalization/SeedOrbit.lean`.

Exact lines 261 to 265. Excerpt `local_action`. Hash in Section 12.

```
theorem local_tensor_action [DecidableEq m] (A : Matrix d d ℂ) (psi : d × m → ℂ) :
    coefficientEquiv ((A ⊗ₖ (1 : Matrix m m ℂ)) *ᵥ psi) = A * coefficientEquiv psi := by
  ext i j
  simp [coefficientEquiv, Matrix.mulVec, dotProduct,
    Fintype.sum_prod_type, Matrix.one_apply, Matrix.mul_apply]
```

The source defines Schmidt rank through product decompositions before proving that it agrees with matrix rank. `HasProductDecomposition C s` means an actual representation

$$C_{ij} = \sum_{a<s} u_a(i) v_a(j).$$

Such a representation factors C through an s-dimensional coordinate space, so rank $C \le s$. Conversely, choose a basis of the row space and express each row in that basis. The basis vectors of the row space and their coordinate functions give a product decomposition of length exactly rank C. These two directions prove that matrix rank is the least possible product length.

Source: `formalization/SeedOrbit.lean`.

Exact lines 298 to 300. Excerpt `schmidt_minimum`. Hash in Section 12.

```
theorem product_length_minimum (C : Matrix d m ℂ) :
    IsLeast {s : ℕ | HasProductDecomposition C s} C.rank := by
  exact ⟨product_decomposition_at_rank C, fun _ h => product_decomposition_rank_bound C h⟩
```

Source: `formalization/SeedOrbit.lean`.

Exact lines 303 to 306. Excerpt `schmidt_definition`. Hash in Section 12.

```
noncomputable def schmidtRank (psi : d × m → ℂ) : ℕ := by
  classical
  exact Nat.find (show ∃ s, HasProductDecomposition (coefficientEquiv psi) s from
    ⟨_, product_decomposition_at_rank _⟩)
```

`Nat.find` takes the least natural number for which a product decomposition exists. The existence needed by `Nat.find` has already been proved at the rank. The equality `schmidt_rank_eq_matrix_rank` then uses the upper witness and the rank lower bound in opposite directions. It is an equality between independently introduced objects.

The reduced B matrix is also constructed explicitly:

$$(\rho_B)_{j\ell} = \sum_i \psi(i,j)\overline{\psi(i,\ell)}.$$

In the chosen convention it is $C^T(C^T)^*$. Its positivity follows from this Gram representation. Its rank agrees with the matrix rank of C, hence with Schmidt rank. Full support is expressed as surjectivity of its multiplication linear map. Combining this with the local orbit dimension gives the endpoint below.

Source: `formalization/SeedOrbit.lean`.

Exact lines 364 to 366. Excerpt `reduced_support`. Hash in Section 12.

```
theorem local_orbit_reduced_support [Nonempty d] (psi : d × m → ℂ) :
    localOrbit psi = ⊤ ↔ LinearMap.range (reducedB psi).mulVecLin = ⊤ := by
  rw [local_orbit_full_iff, reduced_full_support_iff]
```

Contract. The equivalence between a full local orbit and full reduced support assumes `[Nonempty d]`. The dimension equality itself includes zero vectors and empty index types. No normalization of ψ is required for these algebraic rank statements. The action uses every matrix A, so the result concerns the linear span under the local operator algebra. It does not assert reachability under an arbitrary restricted family of unitary controls.

3.4 Addressed bit flips give a computational basis

`Address n` is defined as `Fin n → ZMod 2`, the finite set of bit strings. `State n` is the complex vector space of functions on that address set. The seed is the coordinate vector at the zero address. The linear operator `translation a` evaluates a vector at $x - a$. On a ket it gives $|b\rangle \mapsto |a + b\rangle$.

Each `localX j` translates by the bit vector supported at coordinate j. The operator named `controlledX a j` in this module is selected by the classical address bit a_j: it is identity when that bit is zero, and the local X otherwise. This definition selects a gate according to the address. Despite its name, it does not separately formalize the controlled-NOT gate on two qubits.

The address circuit is the product of this finite gate list. Translation products add their addresses, and the sum of the local address contributions equals a. Therefore the circuit translates by a and sends the zero seed to the coordinate basis vector at a.

Source: `formalization/ComputationalSeed.lean`.

Exact lines 72 to 77. Excerpt `seed_translation`. Hash in Section 12.

```
theorem circuit_eq_translation {n : ℕ} (a : Address n) :
    addressCircuit a = translation a := by
  unfold addressCircuit
  simp_rw [controlledX_eq_translation]
  simpa only [List.map_ofFn, Function.comp_def, List.sum_ofFn, sum_local_addresses] using
    translation_list_product (List.ofFn (fun j : Fin n => Pi.single j (a j)))
```

Source: `formalization/ComputationalSeed.lean`.

Exact lines 80 to 82. Excerpt `seed_basis`. Hash in Section 12.

```
theorem circuit_seed_basis {n : ℕ} (a : Address n) :
    addressCircuit a (seed n) = Pi.basisFun ℂ (Address n) a := by
  rw [circuit_seed, Pi.basisFun_apply, ket]
```

The basis theorem then supplies linear independence and full span. The cardinality theorem gives 2^n. When $n = 0$, the type of bit strings has exactly one empty address, the gate list is empty, and its product is identity. The source covers this case without assuming that the number of qubits is positive.

3.5 Cyclic projectors from powers of an element of finite order

Let $N > 0$ and $S^N = 1$. The source uses `ZMod N` as the residue type and the standard primitive additive character χ. It defines

$$P_j = \frac{1}{N} \sum_{r \in \mathbb{Z}/N} \chi(-rj) S^{r.\mathrm{val}}.$$

The representation `cyclicPowers S` is constructed from the actual powers of S. The proof of its addition law uses $S^N = 1$ to reduce an exponent modulo N. The root of unity is identified with $\exp(2\pi i/N)$, and the coefficient lemma recovers the familiar inverse power ω^{-rj}.

Source: `formalization/CyclicProjectors.lean`.

Exact lines 22 to 26. Excerpt `cyclic_character`. Hash in Section 12.

```

  · exact sum_eq_zero_of_ne_one (isPrimitive_stdAddChar N h)
```

The character sum provides the cancellation needed in the proof. When its argument is zero, the sum is N. When the argument is nonzero, primitivity makes the sum vanish. To prove multiplication of packets, first show that left multiplication by the representation acts on a packet by its character. Substitute that eigenaction into the packet product and collapse the remaining character sum.

Source: `formalization/CyclicProjectors.lean`.

Exact lines 44 to 58. Excerpt `cyclic_mul`. Hash in Section 12.

```
theorem packet_mul (rho : ZMod N → A)
    (hadd : ∀ a b, rho (a+b) = rho a * rho b) (j k : ZMod N) :
    packet rho j * packet rho k = if j=k then packet rho j else 0 := by
  conv_lhs => lhs; unfold packet
  rw [Algebra.smul_mul_assoc, Finset.sum_mul]
  simp only [Algebra.smul_mul_assoc, packet_eigen rho hadd, smul_smul,
    ← map_add_eq_mul]
  have hf (r : ZMod N) : -(r*j) + r*k = (k-j)*r := by ring
  simp only [hf]
  rw [← Finset.sum_smul, character_sum]
  by_cases h : j=k
  · subst k
    simp [NeZero.ne N]
  · have hk : k-j ≠ 0 := sub_ne_zero.mpr (Ne.symm h)
    simp [hk, h]
```

Completeness follows from exchanging the two finite sums and applying the same orthogonality in the other index. Adjointness requires a separate argument in a star ring: conjugate the character, replace r by $-r$, and use the adjoint law for unitary powers. An element of finite order gives the idempotent decomposition. Unitarity supplies the Hermitian condition in the theorem for complex matrices.

Source: formalization/CyclicProjectors.lean.

  refine ⟨hp, hs, ?_, ?_⟩
  · intro j
    simpa only [character_as_power] using he j
  · intro j
    exact cyclic_packet_selfAdjoint S hS hU j
```

Contract. The ambient general construction is a complex algebra over a ring. The concrete endpoint has a finite matrix state index and decidable equality. `[NeZero N]` excludes zero modulus, includes $N = 1$, and justifies division by N. The theorem does not require every packet to have nonzero rank.

3.6 Tensor factors and regrouping by residue

The tensor implementation uses a finite factor index `F`, with a potentially different state index `D i` in every factor. A tensor matrix is defined by the product of its local entries. Multiplication expands into a sum over dependent tuples of intermediate indices. The finite identity expressing a product of sums converts that sum back into the product of local matrix multiplications.

Source: formalization/TensorRefinement.lean.

Exact lines 20 to 27. Excerpt tensor_mul. Hash in Section 12.

```
theorem tensor_mul (A B : (i : F) → Matrix (D i) (D i) ℂ) :
    tensor (fun i => A i * B i) = tensor A * tensor B := by
  ext x y
  simp only [tensor, Matrix.mul_apply]
  rw [Fintype.prod_sum]
  apply Finset.sum_congr rfl
  intro z _
  exact Finset.prod_mul_distrib
```

The product formula, identity formula, adjoint formula and sum formula then prove that the fine packets indexed by tuples are mutually orthogonal, complete and Hermitian. The coarse construction sums fine packets with the same address. The general proof over a ring shows that grouping an orthogonal resolution by any finite address map remains an orthogonal resolution. For polyphase grouping, the address is the sum of the factor residues in `ZMod N`.

Source: `formalization/TensorRefinement.lean`.

Exact lines 139 to 154. Excerpt `tensor_refinement`. Hash in Section 12.

```
theorem tensor_polyphase_refinement {F : Type*} [Fintype F] [DecidableEq F] {D : F → Type*}
    [∀ i, Fintype (D i)] [∀ i, DecidableEq (D i)]
    (N : ℕ) [NeZero N] (P : (i : F) → ZMod N → Matrix (D i) (D i) ℂ)
    (hmul : ∀ i j k, P i j * P i k = if j = k then P i j else 0)
    (hsum : ∀ i, ∑ j, P i j = 1)
    (hstar : ∀ i j, (P i j).conjTranspose = P i j) :
    let Q := fun a : F → ZMod N => tensor (fun i => P i (a i))
    let C := coarse Q (fun a => ∑ i, a i)
    (∀ r s, C r * C s = if r = s then C r else 0) ∧
      (∑ r, C r) = 1 ∧ (∀ r, (C r).conjTranspose = C r) := by
  classical
  dsimp only
  refine ⟨?_, ?_, ?_⟩
  · exact coarse_mul _ _ (fine_mul P hmul)
  · exact coarse_complete _ _ (fine_complete P hsum)
  · exact coarse_selfAdjoint _ _ (fine_selfAdjoint P hstar)
```

Proof reading. The two `let` bindings expose the fine family Q_a and the coarse family C_r inside the statement. After `dsimp only`, each conclusion is a direct application of the generic coarse theorem to a theorem already proved for the fine family. The code therefore separates tensor construction from finite grouping, which makes the proof reusable.

The input here is a packet resolution in each tensor factor. The preceding theorem can construct these local packets from each factor's cyclic symmetry. The tensor theorem takes the resulting local resolutions as input. Together the two constructions implement the traditional passage from cyclic local packets to a tensor refinement and packets grouped by total residue.

4 Circuit corners, conserved packets, and leakage

4.1 The order of the indices is part of the definition

For a packet resolution P, the corner of an operator is

$$U_{ba} = P_b U P_a.$$

The target index b comes first, and the source index a comes second. Matrix factors act from the right on a vector. The gate list in `QuantumPacketCore` is written latest to earliest, $[U_m, \dots, U_1]$, so its product is $U_m \cdots U_1$. The source comments and definitions make both conventions explicit. They determine the orientation of every path.

Contract. The basic corner identities require an arbitrary ring `R` and a finite packet index with decidable equality. They require the packet multiplication and completeness laws, but neither an adjoint nor a norm. The coefficients are generally noncommutative.

Inserting $\sum_c P_c = 1$ between two operators gives

$$(UV)_{ba} = \sum_c U_{bc} V_{ca}.$$

The code first rewrites an individual product of corners. The adjacent $P_c P_c$ collapses by idempotence, while all other factors keep their order. Only then does it combine the finite sum and use completeness.

Source: `formalization/QuantumPacketCore.lean`.

Exact lines 41 to 50. Excerpt `compose_blocks`. Hash in Section 12.

```
theorem compose_blocks (U V : R) (b a : I) :
    P.block (U * V) b a = ∑ c, P.block U b c * P.block V c a := by
  have term (c : I) : P.block U b c * P.block V c a =
      P.proj b * U * P.proj c * V * P.proj a := by
    unfold block
    calc
      _ = P.proj b * U * (P.proj c * P.proj c) * V * P.proj a := by noncomm_ring
      _ = _ := by rw [P.idempotent]
  simp_rw [term]
  simp only [← Finset.sum_mul, ← Finset.mul_sum, P.sum_proj, block, mul_assoc, one_mul]
```

This is the local mechanism for the whole path expansion. `pathSum` is an explicit recursively nested finite sum. For no gates, its value is $P_b P_a$, preserving the boundary packet. For a gate U followed by a shorter circuit, it sums U_{bc} times the shorter path from a to c.

Source: `formalization/QuantumPacketCore.lean`.

Exact lines 63 to 68. Excerpt `circuit_path`. Hash in Section 12.

```
theorem circuit_path_expansion (Us : List R) (b a : I) :
    P.block (circuit Us) b a = P.pathSum Us b a := by
  induction Us generalizing b a with
  | nil => simp [circuit, pathSum, block]
  | cons U Us ih =>
      simp only [circuit, pathSum, P.compose_blocks, ih]
```

Proof reading. The induction generalizes both boundary indices, which makes the induction hypothesis available at every intermediate c. The empty case reduces the identity corner. In the nonempty case, the lemma for composing corners creates the finite sum required by the recursive definition. The induction hypothesis then replaces each shorter corner. The resulting proof covers every finite circuit depth.

Summing the resulting path values over source and target reconstructs the complete circuit operator. It retains coherent complex amplitudes and operator products. No step converts the path sum into a stochastic transition law or assumes that different paths are mutually incoherent.

4.2 The two unitarity identities use different hypotheses

To take adjoints, supply the structure of a star ring and self-adjoint packet elements. The adjoint swaps source and target:

$$U^*_{ba} = (U^*)_{ab}.$$

For the column identity, the source needs only $U^*U = 1$:

$$\sum_b U^*_{ba} U_{bc} = \delta_{ac} P_a.$$

For the row identity, it needs $UU^* = 1$:

$$\sum_a U_{ba} U^*_{da} = \delta_{bd} P_b.$$

The source states these separately rather than hiding both inside a single unitary predicate. The distinction matters in abstract star rings where a one-sided inverse need not be two-sided.

Source: `formalization/QuantumPacketCore.lean`.

Exact lines 119 to 131. Excerpt `unitarity_columns`. Hash in Section 12.

```
theorem unitarity_columns (U : R) (hU : star U * U = 1) (a c : I) :
    (∑ b, star (P.block U b a) * P.block U b c) =
      if a = c then P.proj a else 0 := by
  have term (b : I) : star (P.block U b a) * P.block U b c =
      P.proj a * star U * P.proj b * U * P.proj c := by
    rw [P.adjoint_block hstar]
    unfold block
    calc
      _ = P.proj a * star U * (P.proj b * P.proj b) * U * P.proj c := by noncomm_ring
      _ = _ := by rw [P.idempotent]
  simp_rw [term]
  rw [← Finset.sum_mul, ← Finset.sum_mul, ← Finset.mul_sum, P.sum_proj, mul_one]
  rw [mul_assoc (P.proj a), hU, mul_one, P.mul_proj]
```

Proof reading. The local term is reorganized to $P_a U^* P_b U P_c$, using self-adjointness and $P_b^2 = P_b$. Summing over b replaces the middle resolution by the identity. The given equation $U^*U = 1$ removes the operator factors. The final packet multiplication gives the conditional expression in the conclusion. The concrete matrix wrappers merely specialize this already proved identity.

For an actual state, this identity can be combined with the inner product on the Hilbert space to interpret conservation of total packet probability. The formal statement displayed here is the operator

identity. A chosen vector, state normalization and the corresponding interpretation through the inner product are additional data in such an application.

4.3 Exact commutation propagates to the actual exponential

If H commutes with each P_a, its corners between distinct packets vanish and the diagonal corners reconstruct H. The dynamics layer uses a normed complex algebra and the exponential defined by its power series. A `Commute` proof for H and P_a propagates through complex scalar multiplication and the exponential. Thus e^{zH} is diagonal in the same packet resolution for every complex scalar z.

Source: `formalization/QuantumPacketCore.lean`.

Exact lines 168 to 171. Excerpt `symmetry_exp`. Hash in Section 12.

```
theorem symmetry_exponential_no_transfer (H : R)
    (hH : ∀ i, H * P.proj i = P.proj i * H) (z : ℂ)
    (b a : I) (hba : b ≠ a) : P.block (NormedSpace.exp (z • H)) b a = 0 :=
  P.symmetry_no_transfer _ (P.symmetry_exponential_commutes H hH z) b a hba
```

For evolution in real time, set $z = -it$. The conclusion is exact zero transfer between distinct packets. The commutation hypothesis is still required. It can be proved from a chosen symmetry or supplied as data. A packet resolution alone does not imply it.

4.4 Leakage begins with a differentiated conjugation

The quantitative result works first in an abstract complex C-star algebra. Its matrix specialization activates the operator norm on the Hilbert space through `Matrix.Norms.L2Operator`. This scope is essential: the displayed bound is not an arbitrary entrywise matrix norm estimate.

Let $G^* = -G$ and set $V(t) = e^{tG}Pe^{-tG}$. The source constructs this function and differentiates the actual exponential product:

$$V'(t) = e^{tG}(GP - PG)e^{-tG}.$$

It proves that the exponentials are unitary. Left and right multiplication by unitary elements preserve the C-star norm, so $\|V'(t)\| = \|GP - PG\|$.

theorem transported_derivative (G P : A) (t : ℝ) :
    HasDerivAt (transported G P)
      (exp (t • G) * (G * P - P * G) * exp (t • (-G))) t := by
  have hd := ((hasDerivAt_exp_smul_const G t).mul_const P).mul
    (hasDerivAt_exp_smul_const' (-G) t)
  convert hd using 1
  · rfl
  · noncomm_ring
```

Source: formalization/LeakageBound.lean.

Exact lines 46 to 54. Excerpt transport_lipschitz. Hash in Section 12.

```
theorem transported_lipschitz (G P : A) (hG : star G = -G) (t s : ℝ) :
    ‖transported G P t - transported G P s‖ ≤
      |t-s| * ‖G*P-P*G‖ := by
  have hh := Convex.norm_image_sub_le_of_norm_deriv_le
    (f := transported G P) (s := Set.univ)
    (fun x _ => (transported_derivative G P x).differentiableAt)
    (fun x _ => (transported_derivative_norm G P hG x).le)
    convex_univ (Set.mem_univ s) (Set.mem_univ t)
  simpa [Real.norm_eq_abs, mul_comm] using hh
```

Proof reading. The Lipschitz proof applies a mean-value norm inequality on the convex set of all real times. The existence of the derivative follows from transported_derivative, and its uniform derivative bound comes from transported_derivative_norm. Both are proved for the actual function. Taking one time to be zero gives a bound for $V(t)-P$. Multiplying by e^{tG} converts it into a bound for $e^{tG}P-Pe^{tG}$.

For an orthogonal projection,

$$(1-P)UP=(1-P)(UP-PU)P.$$

The two projection norms are at most one. Hence the leakage corner is bounded by the exponential commutator. Substitute $G=-iH$ for self-adjoint H. Its commutator norm equals the norm of $HP-PH$. This gives the concrete endpoint.

Source: formalization/LeakageBound.lean.

Exact lines 167 to 171. Excerpt leakage_matrix. Hash in Section 12.

```
theorem matrix_commutator_leakage_bound {n : Type*} [Fintype n] [DecidableEq n]
    (H P : Matrix n n ℂ) (hH : H.IsHermitian) (hP : P.IsHermitian)
    (hPP : P*P=P) (t : ℝ) :
    ‖(1-P) * exp ((-(t : ℂ)*Complex.I) • H) * P‖ ≤ |t| * ‖H*P-P*H‖ := by
  exact commutator_leakage_bound H P hH.isSelfAdjoint ⟨hPP, hP.isSelfAdjoint⟩ t
```

Contract. The matrix index may be empty. H must be Hermitian and P must be both Hermitian and idempotent. Time is every real t, including zero and negative times. The proof does not divide by projector rank, dimension or time, so it includes $P=0$ and $P=1$. The estimate concerns a fixed generator H and its exponential, rather than a general time-dependent propagator.

The same file proves a cap at one, giving $\min(1,|t|\|[H,P]\|)$, and exact zero leakage when the commutator is zero. If $H=H_0+V$ with $[H_0,P]=0$ and both terms self-adjoint, only V contributes to the commutator. The elementary estimate $\|[V,P]\|\le 2\|V\|$ gives the perturbation corollary.

```

4.5 Dephasing and a precisely restricted measurement invariance

The dephasing map is $\Delta(\rho) = \sum_a P_a \rho P_a$. It removes off-diagonal corners and is idempotent. For finite complex matrices, trace duality gives

$$\mathrm{tr}(\Delta(E)\rho) = \mathrm{tr}(E\Delta(\rho)).$$

It follows by expanding the finite sum and cyclically rotating matrix factors inside each trace. The subsequent measurement theorem supplies the condition $\Delta(E) = E$, which says precisely that the observable is block diagonal.

Source: `formalization/QuantumPacketCore.lean`.

Exact lines 208 to 211. Excerpt `measurement`. Hash in Section 12.

```
theorem measurement_invariance (E rho : Matrix n n ℂ) (hE : P.dephase E = E) :
    Matrix.trace (E * rho) = Matrix.trace (E * P.dephase rho) := by
  rw [← hE] at ⊢
  simpa only [P.dephase_idempotent] using dephase_trace_duality P (P.dephase E) rho
```

Neither positivity nor a trace of one for ρ is needed for this algebraic identity. Calling it a probability equality requires an appropriate state and effect in the application. Taking $E = 1$ proves trace preservation, since completeness and idempotence give $\Delta(1) = 1$. General observables with off-diagonal packet components need not satisfy the invariance premise. Dephasing may change their expectation values.

This chapter explains why the finite core begins with a resolution in a ring and only adds hypotheses when a later operation needs them. The exact circuit formula, conservation identities, exponential dynamics and leakage bound are related constructions. Each theorem states the hypotheses needed for its own conclusion.

5 Moving frames and an actual projected connection

5.1 Differentiate the coordinates before rewriting the equation

Let $U(t)$ be a unitary frame of finite complex matrices and $\psi(t)$ an actual differentiable vector. With $y(t) = U(t)^*\psi(t)$, the effective Hamiltonian is

$$H_{\text{eff}} = U^*HU - iU^*\dot{U}.$$

The source uses real time derivatives of complex-valued entries. The variables `dU` and `dpsi` are candidate derivative values, and the hypotheses `HasDerivAt` assert that they are the actual derivatives at the specified time.

Source: `formalization/MovingFrames.lean`.

Exact lines 23 to 29. Excerpt `frame_product`. Hash in Section 12.

```
theorem matrix_vector_derivative (A : ℝ → Matrix n n ℂ) (y : ℝ → n → ℂ)
    (dA : Matrix n n ℂ) (dy : n → ℂ) (t : ℝ)
    (ha : ∀ i j, HasDerivAt (fun s => A s i j) (dA i j) t)
    (hy : ∀ i, HasDerivAt (fun s => y s i) (dy i) t) (i : n) :
    HasDerivAt (fun s => (A s *ᵥ y s) i) ((dA *ᵥ y t + A t *ᵥ dy) i) t := by
  simpa only [Matrix.mulVec, dotProduct, Pi.add_apply, Pi.mul_apply, Finset.sum_add_distrib] using
    HasDerivAt.fun_sum (u := Finset.univ) (fun j _ => (ha i j).mul (hy j))
```

Proof reading. The proof applies the scalar product rule to each summand of the product of a matrix and a vector, then differentiates the finite sum. It produces the two expected terms without assuming differentiability of the transformed coordinates in advance. The lemma for differentiating an adjoint conjugates the derivative of the transposed entry. It uses the fact that conjugation is linear over the real numbers.

Differentiating $U^*U = 1$ gives $\dot{U}^*U + U^*\dot{U} = 0$, so $U^*\dot{U}$ is skew-adjoint and $-iU^*\dot{U}$ is Hermitian. The conjugated term U^*HU is Hermitian when H is Hermitian. That last premise is explicitly present in the final source. Unitarity of U by itself does not establish Hermiticity of an arbitrary H.

Source: `formalization/MovingFrames.lean`.

Exact lines 110 to 132. Excerpt `moving_coordinates`. Hash in Section 12.

```
theorem moving_frame_coordinates [DecidableEq n]
    (U : ℝ → Matrix n n ℂ) (psi : ℝ → n → ℂ)

    let dy := dU.conjTranspose *ᵥ psi t + (U t).conjTranspose *ᵥ dpsi
    (∀ i, HasDerivAt (fun s => y s i) (dy i) t) ∧
      Complex.I • dy = effectiveHamiltonian (U t) H dU *ᵥ y t ∧
```

```
    (effectiveHamiltonian (U t) H dU).conjTranspose =
      effectiveHamiltonian (U t) H dU := by
  dsimp only
  have hy := matrix_vector_derivative (fun s => (U s).conjTranspose) psi
    dU.conjTranspose dpsi t (adjoint_derivative U dU t hu) hp
  refine ⟨hy, ?_, effective_hamiltonian_hermitian U H dU t hu hleft hH⟩
  apply moving_frame_equation U psi (fun s => (U s).conjTranspose *ᵥ psi s)
    H dU dpsi _ t hu hp hy (hleft t) _ hsch
  intro s
  rw [Matrix.mulVec_mulVec, hright, Matrix.one_mulVec]
```

Contract. The matrix index is finite with decidable equality. Entrywise derivative hypotheses are at one real time t. Both unitary identities hold for every time, permitting construction of the inverse coordinates. The original Schrödinger equation $i\dot{\psi} = H\psi(t)$ is a premise, and $H^* = H$ is the premise for the Hermiticity conclusion. The theorem constructs y, constructs its derivative and proves its equation. Existence of a solution for arbitrary initial data is a separate question.

Proof reading. After unfolding the two `let` expressions, the proof obtains the actual derivative of $U^*\psi$ from the product rule. It gives that derivative proof to `moving_frame_equation`. Unitarity on the right reconstructs $\psi = Uy$, while unitarity on the left removes U^*U when the differentiated equation is multiplied by U^*. The separate Hermiticity lemma uses the differentiated unitary identity and the supplied Hermiticity of H.

5.2 The canonical connection derives its identities for first derivatives

For a differentiable complete orthogonal family $P_a(t)$, write $D_a = \dot{P}_a(t)$. Differentiating multiplication gives

$$D_a P_b + P_a D_b = \delta_{ab} D_a.$$

Differentiating completeness gives $\sum_a D_a = 0$. Differentiating self-adjointness gives $D_a^* = D_a$. These are consequences of actual derivatives of the original functions.

Contract. The theorem for actual derivatives works in a normed real algebra with a star ring structure, compatible real scalar action and continuous involution. The finite packet index has decidable equality. The projector multiplication, completeness and adjoint identities hold for all real times. This theorem treats a curve of projectors. Manifold curvature is developed in the later modules.

The skew-adjointness calculation sums $D_a P_a + P_a D_a = D_a$. Their sum vanishes, giving $C + C^* = 0$. The commutator calculation first isolates $C P_b = D_b P_b$, then obtains $D_b + P_b C = D_b P_b$ from the differentiated multiplication identities and completeness. Subtracting gives the desired commutator. The factor of one half uses the real scalar structure and the same zero sum.

5.3 The off-diagonal derivative block

For an idempotent P that varies with a parameter, differentiating $P^2 = P$ in direction v gives

$$D_v P\, P + P\, D_v P = D_v P.$$

Multiplying this equation by P and cancelling an identical summand gives $P(D_v P)P = 0$. The curvature calculation therefore uses a consequence of idempotence and differentiation.

  have hh := congrArg (fun z => P*z) hD
  simp only [mul_add, ← mul_assoc, hP] at hh
  exact add_eq_right.mp hh
```

For a range section s with $Ps = s$, differentiating the range condition gives

$$D_v s = (D_v P)s + P(D_v s).$$

The chart connection is $\nabla_X s = P(D_X s)$. Its curvature is the actual commutator

$$R(X,Y)s = \nabla_X \nabla_Y s - \nabla_Y \nabla_X s - \nabla_{[X,Y]} s.$$

The bracket term is essential: it cancels the change in the vector fields in the second directional derivatives. The proof uses Mathlib's actual Fréchet derivative and actual Lie bracket, rather than independently supplied coefficients of second order.

  simp [curvatureForm, hPs, map_sub]
```

Contract. The local theorem has real normed model and fiber spaces. P, X and Y are differentiable at the specified point. The section s is twice continuously differentiable there. The idempotent equation

and the equation expressing that the section lies in the range hold as functions. An earlier theorem in global chart coordinates assumes global differentiability. The local variant supports use inside arbitrary chart neighborhoods.

Proof reading. Expand the derivative of the projected directional derivative by the product rule. The derivative identity for the Lie bracket cancels the second derivatives of s and the derivatives of X, Y. Substitute the differentiated identity for a section in the range into the two remaining terms involving first derivatives. The components $P(D_v P)P(D_w s)$ vanish by the sandwich lemma. The surviving term is $P[(D_X P), (D_Y P)]s$, and $Ps = s$ puts the final right-hand P into the curvature form.

5.4 Build the range atlas from the projector

The global development begins with an operator family $P : M \to \mathcal{L}_{\mathbb{R}}(F, F)$. Its fiber is the fixed subspace $\{v : P(x)v = v\}$ with the subspace topology. The total space is the subtype of $M \times F$ consisting of such fixed pairs. The atlas is constructed from P rather than supplied as a hypothesis.

For idempotents p, q, define

$$T(p, q) = pq + (1 - p)(1 - q).$$

This is identity at $p = q$, and it intertwines the two projectors. Near a base point a, the map $T(P(x), P(a))$ is invertible because invertibility is open in the complete operator algebra and it is identity at $x = a$.

```
theorem transport_intertwines (p q : F →L[ℝ] F) (hp : p*p=p) (hq : q*q=q) :
    p*transport p q=transport p q*q := by
  unfold transport
  have ha : p*(p*q)=p*q := by rw [← mul_assoc,hp]
  have hb : p*(q*q)=p*q := by rw [hq]
  noncomm_ring [hp,hq,ha,hb]
```

Let $U_a = \{x : T(P(x), P(a)) \text{ is invertible}\}$. Reconstruction transports the fixed fiber at a into the ambient space at x. Coordinates apply the inverse transport and project to the fixed fiber at a. The intertwiners show that both maps land in the correct fibers. On U_a, the two inverse identities follow from genuine inverse cancellation.

    exact ((hx.prodMk (hc.clm_apply hv)).subtype_mk _).subtype_mk _
```

This declaration is a homeomorphism from the restricted actual total space to $U_a \times \mathrm{fiber}(P(a))$. In addition to inverse laws, it proves continuity in both directions using the smooth coordinate and reconstruction maps. Transitions are composed from these actual maps. They are continuous linear maps in each fiber, smooth in the base, and satisfy the cocycle law by cancelling the reconstruction and coordinate maps in the middle.

```

Contract. The construction of the range atlas uses a smooth real projector map on a charted parameter space and a complete real normed fiber space. This bundle construction requires idempotence and

does not require self-adjointness. The explicit atlas theorem does not demand a global chart. Local linear fiber equivalences prove local constancy of finite rank whenever finite rank is being interpreted. The underlying fiber equivalence is the stronger structural statement.

The implementation uses this explicit smooth atlas directly. It does not package it as a Mathlib `ContMDiffVectorBundle` instance. The total space, open domains, local product homeomorphisms, transitions and their identities are all constructed and proved. The distinction concerns how these results are packaged in Lean.

5.5 The global derivative and gauge gluing

On the manifold, the global connection is defined using `mvfderiv`, the derivative of a map from a manifold to a vector space. A tangent vector at x has type `TangentSpace I x`, so a vector field is a dependent function giving one such vector at every point.

  simp [nabla,mvfderiv_smul hc hs,hPs,add_comm]
```

The global range property follows immediately from idempotence. Additivity in sections uses actual differentiability premises. The Leibniz rule needs the range condition for $s(x)$ because the scalar derivative term initially contains $P(x)s(x)$. Linearity in the vector field uses linearity of the derivative. A germ lemma says that locally equal functions have the same covariant derivative at the point.

Local coordinate connections reconstruct a range section, differentiate it globally and then take coordinates. On an open domain, local reconstruction equals the original section in a neighborhood. The germ lemma therefore identifies the local and global connection. On an overlap, coordinate transitions carry one representation into the other.

  rw [fromCoord_toCoord P hPP a x hx.1 _ (nabla_in_range I P hPP X _ x)]
```

The equivalence for smooth sections needs only an eventual range condition near the point, not an unproved globally extended section. The gauge law in the completion file applies to arbitrary local coordinate functions and compares their reconstructed connection values on an overlap. It is not restricted to a prechosen global frame.

5.6 Manifold curvature and its endpoint

The final curvature theorem uses a smooth real boundaryless manifold modeled on a complete real normed space E. The model is $\mathcal{J}(\mathbb{R}, E)$. The manifold has `ChartedSpace E M` and a smooth `IsManifold` instance for that model. The source pulls vector fields into a chart centered at the point, identifies the manifold derivative and bracket with their chart versions, and then proves the cancellation using actual manifold operations.

  simp only [map_add,hz,add_zero]
  simp [curvatureForm,hPs,map_sub]
```

Contract. Here P, the two vector fields and the ambient range section are smooth. The equations $P(x)^2 = P(x)$ and $P(x)s(x) = s(x)$ are given globally. The conclusion is $R(X, Y)s = P(dP \wedge dP)P\,s$ at an arbitrary point. The final manifold curvature endpoint assumes no global chart, no supplied curvature identity and no supplied range atlas. The atlas portion separately requires completeness of the fiber space. Finite complex quantum spaces fit by restriction to their underlying real spaces.

The next theorem proves tensoriality: replacing the two fields and the section by smooth extensions with the same values at the point leaves curvature unchanged. The completion file makes the curvature form alternating and linear over the real numbers, proves it maps into the actual fiber, and defines the resulting continuous linear fiber endomorphism. Constant projector maps, including zero and identity, have zero curvature form.

The six files on projected geometry follow this mathematical development. `ProjectedCurvature` establishes the algebra and calculus on the parameter space. `LocalProjectedCurvature` makes the hypotheses local, and `GlobalRangeBundle` constructs the atlas. `GlobalProjectedConnection` defines the connection and proves that its local descriptions agree. `ManifoldProjectedCurvature` proves the global curvature formula. Finally, `ProjectedBundleCompletion` proves compatibility with intrinsic sections, gauge transformations and the curvature form on each fiber. The later global constructions extend the results of the earliest chart file.

6 Finite channels and the full Knill–Laflamme criterion

6.1 Complete positivity has an actual amplification map

For finite complex matrices, the Kraus channel is the map

$$\Phi(\rho) = \sum_a K_a \rho K_a^*.$$

Its additivity and complex homogeneity construct an actual linear map. Each summand preserves positive semidefiniteness by a matrix congruence, so the finite sum is positive. Trace preservation is a separate theorem under $\sum_a K_a^* K_a = 1$, proved by cyclic trace rotation and completeness of that Kraus sum.

To prove complete positivity the source does not merely restate positivity. It defines blockwise amplification on matrices indexed by $J \times n$ and identifies it entrywise with the actual Kraus family $1_J \otimes K_a$.

Source: `formalization/KrausChannels.lean`.

Exact lines 48 to 56. Excerpt `kraus_amplify`. Hash in Section 12.

```
theorem amplification_eq_kraus {J : Type*} [Fintype J] [DecidableEq J]
    (K : A → Matrix n n ℂ) (rho : Matrix (J × n) (J × n) ℂ) :

    (K : A → Matrix n n ℂ) {rho : Matrix (J × n) (J × n) ℂ}
    (hrho : rho.PosSemidef) : (amplify (channel K) rho).PosSemidef := by
  rw [amplification_eq_kraus]
  exact channel_positive _ hrho
```

Contract. The system and Kraus index types are finite. The reference type `J` is an arbitrary finite type with decidable equality. Complete positivity itself does not require Kraus normalization. Normalization is needed for trace preservation and preservation of density matrices. Every finite reference dimension is quantified in the theorem, rather than sampled in an example. Infinite reference systems are not encoded by these finite matrix declarations.

Proof reading. The amplification identity expands entries of a Kronecker product, uses the identity matrix to force equality of the reference indices, and collapses the corresponding sums. Once amplification is literally a Kraus map, the earlier positivity theorem applies without a new positivity hypothesis about the amplified channel.

6.2 Orthogonal syndromes are the recovery stage

The recovery construction begins with a code projection P and an orthogonal normalized family E_a satisfying

$$E_a P = E_a, \qquad E_a^* E_b = \delta_{ab} P.$$

Their output packets $Q_a = E_a E_a^*$ are orthogonal star projections. Their sum Q is a star projection and $Q^\perp = 1 - Q$ is its complement.

Source: `formalization/SyndromeRecovery.lean`.

Exact lines 21 to 27. Excerpt `syndrome_structure`. Hash in Section 12.

```
structure OrthogonalSyndromes (R I : Type*) [Ring R] [StarRing R]
    [Fintype I] [DecidableEq I] where
  code : R
  code_projection : IsStarProjection code
  error : I → R
  restricted : ∀ a, error a * code = error a
  gram : ∀ a b, star (error a) * error b = if a=b then code else 0
```

The decoder is

$$\mathcal{R}(\sigma) = \sum_a E_a^* \sigma E_a + Q^\perp \sigma Q^\perp.$$

The complement term is important. Without it the decoder would generally lose trace on input outside the sum of syndrome output spaces. The implementation uses `Option I` to index the complete Kraus family for recovery: `some a` denotes E_a^*, and `none` denotes $Q^\perp$. Thus the extra branch is encoded in the actual finite family.

Source: `formalization/SyndromeRecovery.lean`.

Exact lines 84 to 90. Excerpt `syndrome_complete`. Hash in Section 12.

```
theorem recoveryKraus_complete :
    (∑ a, star (S.recoveryKraus a)*S.recoveryKraus a) = 1 := by
  rw [Fintype.sum_option]
  simp only [recoveryKraus, star_star, S.complement_projection.isSelfAdjoint.star_eq,
    S.complement_projection.isIdempotentElem.eq]
  change S.complement + S.total = 1
  simp [complement]
```

Proof reading. The sum over `Option I` splits into the complement branch and the syndrome branches. Self-adjointness and idempotence turn the complement contribution into $Q^\perp$. The syndrome contribution is Q. Their sum is the identity. This proves trace preservation on the entire ambient matrix space, not merely on noisy code states.

For an arbitrary operator supported on the code, $P\rho P = \rho$, the decoder of a cross error is

$$\mathcal{R}(E_a \rho E_b^*) = \delta_{ab} \rho.$$

The orthogonal Gram law kills every nonmatching syndrome contribution, and the complement annihilates each error output.

Source: `formalization/SyndromeRecovery.lean`.

Exact lines 103 to 124. Excerpt `syndrome_cross`. Hash in Section 12.

```
theorem decoder_cross_error (rho : R) (hrho : S.code*rho*S.code=rho) (a b : I) :
    S.decoder (S.error a*rho*star (S.error b)) = if a=b then rho else 0 := by
  have hc (c : I) :

      · simp [hab, Ne.symm hab]
    · simp [hca]
  have hq : S.complement*(S.error a*rho*star (S.error b))*S.complement=0 := by
    calc
      _ = (S.complement*S.error a)*rho*(star (S.error b)*S.complement) := by
        noncomm_ring
      _ = 0 := by rw [S.complement_error, zero_mul, zero_mul]
  simp only [decoder, hc, hq, add_zero]
  simp
```

Over an abstract star ring, this gives an algebraic correction identity. The construction for complex matrices additionally proves positivity, trace preservation, complete positivity at every finite reference dimension and preservation of density matrices. A weighted normalized mixture and a coherent error superposition are then handled by linearity and the formula for cross errors.

This file alone would prove recovery for supplied orthogonal syndrome data. It would not prove that arbitrary Knill–Laflamme Gram data can be put into that form, and it would not prove necessity of the Gram condition. The current source has separate modules for those obligations.

6.3 General Gram data are not assumed diagonal

The finite Knill–Laflamme data consist of a star projection P, errors E_a, and a positive semidefinite coefficient matrix C with

$$PE_a^*E_bP = C_{ab}P.$$

No invertibility of C is required. The matrix can be singular and can have off-diagonal coefficients.

Source: `formalization/KnillLaflammeSufficiency.lean`.

Exact lines 187 to 193. Excerpt `kl_data`. Hash in Section 12.

```
structure Data (n I : Type*) [Fintype n] [DecidableEq n] [Fintype I] [DecidableEq I] where
  code : Matrix n n ℂ
  code_projection : IsStarProjection code
  error : I → Matrix n n ℂ
  gramMatrix : Matrix I I ℂ
```

```
  gram_positive : gramMatrix.PosSemidef
  gram : ∀ a b, code * star (error a) * error b * code = gramMatrix a b • code
```

First restrict each error to the code by replacing E_a with $E_a P$. This changes neither the noisy output of a supported operator nor its compressed Gram data. The source's `mix E U r` uses the columns of U as the new error coordinates. It proves that mixing transforms the Gram matrix to $U^* C U$ and that unitary mixing leaves the Kraus noise map unchanged.

The actual Hermitian spectral theorem supplies `eigenvectorUnitary` and real eigenvalues. Positive semidefiniteness proves those eigenvalues are nonnegative. The declaration below constructs the diagonal error data directly from that spectral information.

Source: `formalization/KnillLaflammeSufficiency.lean`.

Exact lines 204 to 214. Excerpt `kl_diagonal`. Hash in Section 12.

```
noncomputable def diagonal : DiagonalErrors n I where
  code := K.code
  code_projection := K.code_projection
  error := mix (fun a => K.error a*K.code)
    (K.gram_positive.isHermitian.eigenvectorUnitary : Matrix I I ℂ)
  restricted := mix_restricted K.code (fun a => K.error a*K.code)
    (fun a => by rw [mul_assoc, K.code_projection.isIdempotentElem.eq]) _
  weight := K.gram_positive.isHermitian.eigenvalues
  nonnegative := K.gram_positive.eigenvalues_nonneg
  gram := diagonalized_gram K.code (fun a => K.error a*K.code) K.gramMatrix
    K.gram_positive K.restricted_error_gram
```

Proof reading. The `error` field mixes the errors restricted to the code by the spectral unitary. The `weight` field uses the actual eigenvalues. The `gram` field applies the proved diagonalization identity. The `restricted` field uses idempotence of the code projector, and the `nonnegative` field comes from positivity of the input Gram matrix. These fields construct the required diagonal data.

6.4 Singular directions are eliminated without division by zero

If a diagonal weight is zero, the corresponding restricted error satisfies $E^* E = 0$. For finite complex matrices this forces $E = 0$. Therefore the construction does not normalize a zero spectral direction.

Source: `formalization/KnillLaflammeSufficiency.lean`.

Exact lines 107 to 110. Excerpt `kl_null`. Hash in Section 12.

```
theorem zero_weight_error (a : I) (ha : D.weight a = 0) : D.error a = 0 := by
  have hh : star (D.error a) * D.error a = 0 := by
    simpa only [ite_true, ha, Complex.ofReal_zero, zero_smul] using D.gram a a
  exact Matrix.conjTranspose_mul_self_eq_zero.mp hh
```

The active index is the subtype `{a : I // 0 < D.weight a}`. For an active error define $F_a = \lambda_a^{-1/2} E_a$. The source proves the square root is nonzero and its square equals the weight before using its inverse. The normalized errors satisfy $F_a^* F_b = \delta_{ab} P$, so the preceding syndrome construction applies.

For an unnormalized original error family, the decoder corrects the noise to the exact scale

$$\mathcal{R}\left(\sum_a E_a \rho E_a^*\right) = \operatorname{tr}(C)\rho.$$

Unitary mixing preserves the noise, the restricted noise agrees on the code, and the spectral eigenvalue sum is the trace of C. If the original errors form a normalized channel and $P \neq 0$, compressing the Kraus completeness relation gives $\operatorname{tr}(C)P = P$, so the scale is one. If $P = 0$, every supported operator is zero and the correction assertion follows directly.

Source: `formalization/KnillLaflammeSufficiency.lean`.

Exact lines 252 to 259. Excerpt `kl_corrects`. Hash in Section 12.

```
theorem recovery_corrects (hcomplete : (∑ a, star (K.error a)*K.error a) = 1)
    (rho : Matrix n n ℂ) (hrho : K.code*rho*K.code=rho) :
    K.diagonal.syndromes.decoder (noise K.error rho) = rho := by
  rw [K.recovery_noise_scaled rho hrho]
  by_cases hp : K.code = 0
  · have hr : rho=0 := by simpa [hp] using hrho.symm
    simp [hr]
  · rw [K.gram_trace_one hp hcomplete, one_smul]
```

Contract. This sufficiency statement assumes finite complex matrices, a star code projection, a positive Gram matrix and its compressed Gram relation, together with global Kraus normalization for exact channel correction with scale one. The correction conclusion covers all operators supported on the code, including those that are not positive. The decoder is an actual finite CPTP extension on the whole space. Its spectral construction is mathematical and noncomputable. The theorem supplies neither a numerical eigenvalue routine nor a performance guarantee for an executable decoder.

6.5 Necessity starts from actual recovery

The reverse implication takes a finite recovery family R_r with $\sum_r R_r^* R_r = 1$, and assumes its actual composite Kraus map fixes every operator supported on the code. It must derive the Gram condition rather than take it as a premise.

The key rigidity lemma says that if A^*A is the rank-one Gram matrix of a vector p, then every row of A is a scalar multiple of p. If $p = 0$, positivity gives $A = 0$. Otherwise choose a nonzero coordinate p_t. A vector supported in two coordinates and orthogonal to p is in the kernel of A^*A, hence of A. The resulting equation in two coordinates yields the row proportionality.

```
theorem rank_one_gram_rigidity {q J : Type*} [Fintype q] [DecidableEq q]
    [Fintype J] [DecidableEq J] (A : Matrix J q ℂ) (p : q → ℂ)
    (hgram : A.conjTranspose*A = Matrix.vecMulVec (star p) p) :
    ∃ z : J → ℂ, ∀ j t, A j t = z j*p t := by
  by_cases hp : p=0
  · have hA : A=0 := Matrix.conjTranspose_mul_self_eq_zero.mp (by simpa [hp] using hgram)
    exact ⟨fun _ => 0, by simp [hA]⟩
```

```
  · obtain ⟨t,ht⟩ : ∃ t, p t ≠ 0 := Function.ne_iff.mp hp
    refine ⟨fun j => A j t / p t, ?_⟩
    intro j s
    let v : q → ℂ := Pi.single s (p t) - Pi.single t (p s)
    have hpv : p ⬝ᵥ v = 0 := by
      simp [v, dotProduct_sub, dotProduct_single, mul_comm]
    have hav : A *ᵥ v=0 := by
      apply (Matrix.conjTranspose_mul_self_mulVec_eq_zero A v).mp
      rw [hgram]
      ext u
      change (∑ x, star (p u) * p x * v x) = 0
      simp_rw [mul_assoc]
      rw [← Finset.mul_sum]
      change star (p u) * (p ⬝ᵥ v) = 0
      rw [hpv, mul_zero]
    have heq : A j s*p t - A j t*p s=0 := by
      simpa [v, Matrix.mulVec_sub, Matrix.mulVec_single, mul_comm] using congrFun hav j
    change A j s = (A j t / p t) * p s
    field_simp [ht]
    linear_combination heq
```

To apply this to Kraus operators, flatten each operator's entries into a row indexed by a pair of matrix coordinates. Evaluate the asserted map equality on matrix units. This yields the rank-one Gram equality for the flattened matrix. Each composite recovery operator $R_r E_a P$ must therefore be $z_{ra} P$.

Now insert the recovery completeness relation into $P E_a^* E_b P$. It becomes the sum of adjoint products of those composite operators. Their scalar form gives a positive Gram matrix $C = Z^* Z$ with the required coefficients.

  simp_rw [hz, star_smul, hP.isSelfAdjoint.star_eq, smul_mul_assoc,
    mul_smul_comm, smul_smul, hP.isIdempotentElem.eq]
  simp only [Matrix.mul_apply, Matrix.conjTranspose_apply, Finset.sum_smul, Z]
```

Proof reading. The witness Z^*Z is positive by an existing matrix theorem. The intermediate `heq` is obtained by inserting $\sum_r R_r^* R_r = 1$ without reordering the error factors. After rewriting every $R_r E_a P$ as a scalar times P, self-adjointness and idempotence reduce the sum to the entries of Z^*Z times P. Thus positivity is proved from the recovery, not imposed on an unknown matrix.

6.6 The state formulation is bridged to all code operators

A physical criterion is usually stated for density matrices: positive semidefinite, trace one and supported on the code. The necessity argument above uses all operators supported on the code. The source supplies the missing bridge.

First, a nonzero positive matrix has positive nonzero trace. Scaling by the inverse real trace produces a density matrix. Linearity then removes that normalization. Zero positive matrices are handled separately. Next, the complex polarization identity expresses an arbitrary outer product xy^* as a linear combination of pure positive matrices. Finally, matrix units span all matrices. Two maps that are linear over the complex numbers therefore agree on every operator if they agree on all pure states.

open scoped Kronecker
```

Contract. The code is a star projection. The error family is finite and normalized by $\sum_a E_a^* E_a = 1$. The existential Gram matrix must be positive semidefinite and satisfy every compressed cross relation. The theorem permits the zero code. In that case, no nonzero normalized code density matrix exists, and the operator bridge remains valid because the supported operator space is zero.

6.7 Reference systems and error spans

The theorem for finite reference systems identifies each reference block of $1 \otimes \mathcal{R}$ and $1 \otimes \mathcal{E}$ with the corresponding system noise map. The supported reference matrix condition implies each system block is supported on the code, so the operator correction theorem applies block by block.

```

It follows that the same correction identity holds for entangled states with any finite reference system. The displayed algebraic identity requires neither positivity nor a trace of one. These conditions can be supplied to interpret the matrix as a density state. This is stronger than checking only product states and does not rely on assuming separability.

The module for recovery on the error span keeps track of cross coefficients. With the source's Gram orientation,

$$\mathcal{R}(E_a \rho E_b^*) = C_{ba} \rho.$$

The reversed indices are deliberate. Expanding a coherent combination produces the scalar $\sum_{a,b} c_a \overline{c_b} C_{ba}$. Summing such expressions over a new Kraus family F_j in the old error span gives a common scalar multiplier. If the new family is normalized, trace preservation forces that multiplier to one on a nonzero code. For the zero code, the only supported operator is again zero.

This is one fixed recovery correcting every normalized channel in the error span, with the coefficients explicitly witnessing span membership. It does not claim correction with scale one for an arbitrary unnormalized linear combination. For unnormalized error families, the separate criterion requires a nonnegative scale t independent of the supported input operator and proves equivalence with the Gram relation.

The example module checks illustrative finite cases, including singular Gram matrices and Gram matrices that are not diagonal. Those examples help expose conventions, but the general theorem rests on spectral reduction, normalized syndrome recovery, necessity through the rank-one argument, and the bridge from density matrices to operators. The resulting theorem is the full criterion for finite complex matrices under its stated hypotheses. The earlier construction for orthogonal syndromes was one stage of this proof.

7 Effective resolvents, Euclidean transfer, and finite bounds

7.1 A resolvent identity needs two invertibility hypotheses

Split the state index into a retained type P and an eliminated type Q. Let the full operator have blocks $A_{pp}, A_{pq}, A_{qp}, A_{qq}$. The eliminated resolvent block is $D = z1_Q - A_{qq}$, and the Schur complement is

$$S(z) = z1_P - A_{pp} - A_{pq}D^{-1}A_{qp}.$$

The theorem identifies the retained corner of the full inverse with $S(z)^{-1}$. The two assumptions supplied through bracketed type classes assert invertibility of D and invertibility of the full resolvent matrix.

Source: `formalization/SchurFeshbach.lean`.

Exact lines 27 to 44. Excerpt `feshbach`. Hash in Section 12.

```
theorem projected_resolvent (App : Matrix P P ℂ) (Apq : Matrix P Q ℂ)

    [Invertible (Matrix.scalar Q z-Aqq)]
    [Invertible (Matrix.scalar (P ⊕ Q) z-Matrix.fromBlocks App Apq Aqp Aqq)] :
    ((Matrix.scalar (P ⊕ Q) z-Matrix.fromBlocks App Apq Aqp Aqq)⁻¹).submatrix
      Sum.inl Sum.inl = (schur App Apq Aqp Aqq z)⁻¹ := by
  let D := Matrix.scalar Q z-Aqq
  let A := Matrix.scalar P z-App
  have he := resolvent_blocks App Apq Aqp Aqq z
  let : Invertible (Matrix.fromBlocks A (-Apq) (-Aqp) D) := Invertible.copy ‹_› _ he.symm
  let : Invertible (A-(-Apq)*⅟D*(-Aqp)) := Matrix.invertibleOfFromBlocks₂₂Invertible A (-Apq)
   ↪  (-Aqp) D
  have hinv := Matrix.invOf_fromBlocks₂₂_eq A (-Apq) (-Aqp) D
  have hs : A-(-Apq)*⅟D*(-Aqp)=schur App Apq Aqp Aqq z := by
    simp only [Matrix.neg_mul,Matrix.mul_neg,neg_neg,Matrix.invOf_eq_nonsing_inv,schur,D,A]
  rw [he,← Matrix.invOf_eq_nonsing_inv,hinv]
  change ⅟(A-(-Apq)*⅟D*(-Aqp))=(schur App Apq Aqp Aqq z)⁻¹
  rw [Matrix.invOf_eq_nonsing_inv]
  congr 1
```

Contract. Both finite types of state indices have decidable equality. The eliminated block and the full resolvent matrix are invertible. Lean's matrix inverse notation is a total operation, but that notation alone does not supply genuine invertibility at a singular matrix. The theorem uses the invertibility assumptions to justify the actual inverse identities.

Proof reading. First rewrite $z1 - A$ as the displayed block matrix, retaining the negative signs on the two off-diagonal blocks. Copy the given full invertibility instance to that rewritten matrix. A Mathlib theorem for block inverses supplies invertibility of its Schur complement and the full inverse formula. Rewrite the inverse supplied by the invertibility instance as the nonsingular matrix inverse, then select the retained submatrix. The two negative off-diagonal factors multiply to the sign already encoded in the definition of `schur`.

The source retains a concrete counterexample to dropping full invertibility: at $z = 0$ with $H = \mathrm{diag}(0, -1)$, the eliminated resolvent block is 1, while the full matrix $z1 - H = \mathrm{diag}(0, 1)$ is singular.

Source: formalization/SchurFeshbach.lean.

Exact lines 59 to 64. Excerpt feshbach_counterexample. Hash in Section 12.

```
theorem eliminated_invertible_full_singular :
    IsUnit (1 : ℂ) ∧ ¬ IsUnit (!![0, 0; 0, 1] : Matrix (Fin 2) (Fin 2) ℂ) := by
  constructor
  · exact isUnit_one
  · rw [Matrix.isUnit_iff_isUnit_det]
    norm_num [Matrix.det_fin_two]
```

The companion schur_invertible theorem says that, when the eliminated block is invertible, full invertibility is equivalent to invertibility of the Schur complement. This locates the remaining pole rather than assuming it absent. The corrected assumption is part of the checked interpretation of the traditional result. This source reuses the retained Chapter VI proof. The source correspondence is recorded separately.

7.2 Euclidean transfer is defined by the exponential series

The transfer is

$$T_e(t) = \exp(-t(H - e1)).$$

The definition uses the actual matrix exponential. For Hermitian H, a theorem from continuous functional calculus identifies it with the scalar function $x \mapsto e^{-t(x-e)}$ applied to H.

Source: formalization/EuclideanTransfer.lean.

Exact lines 39 to 47. Excerpt euclidean_cfc. Hash in Section 12.

```
theorem transfer_cfc (H : Matrix n n ℂ) (hH : H.IsHermitian) (e t : ℝ) :

    simp only [Algebra.algebraMap_eq_smul_one]
  rw [hlin, CFC.real_exp_eq_normedSpace_exp (shifted_hermitian H hH e t).isSelfAdjoint]
  rfl
```

Proof reading. The proof composes the functional calculus for the exponential with the affine scalar function $-t(x - e)$. It evaluates that affine function through the calculus as $-t(H - e1)$. A theorem relating real continuous functional calculus to the exponential in a normed space identifies the final object with the original power series. The spectral conclusions therefore apply to the actual transfer, not an independently postulated spectral surrogate.

The shift e_0 is the minimum of the actual Hermitian eigenvalues. It is defined only when the finite state index is nonempty, because an empty spectrum has no minimum element. The source proves both membership of e_0 in the spectrum and the assertion that it is a lower bound. Positive definiteness of $T_e(t)$ follows from strict positivity of the scalar exponential for every real t. Semigroup composition follows because the two scaled generators commute.

Source: formalization/EuclideanTransfer.lean.

Exact lines 89 to 96. Excerpt euclidean_endpoint. Hash in Section 12.

```
theorem finite_euclidean_transfer [Nonempty n] (H : Matrix n n ℂ)
    (hH : H.IsHermitian) (t s : ℝ) (ht : 0 ≤ t) :
    (transfer H (groundEnergy hH) t).PosDef ∧
    transfer H (groundEnergy hH) (t+s) =
      transfer H (groundEnergy hH) t * transfer H (groundEnergy hH) s ∧
    spectrum ℝ (transfer H (groundEnergy hH) t) ⊆ Set.Ioc 0 1 := by
  exact ⟨transfer_posDef H hH _ _, transfer_add H _ _ _,
    transfer_spectrum_interval H hH _ _ ht (ground_energy_le hH)⟩
```

Contract. The endpoint assumes a nonempty finite state index, Hermitian H and nonnegative t. It includes $t = 0$. The other time s is arbitrary real in the semigroup identity. Spectral containment in $(0, 1]$ uses $t \geq 0$ and the shift by the ground energy. A separate endpoint states containment for the complex spectrum as the real interval's complex image. No infinite-dimensional transfer or continuum limit is concluded.

7.3 The low-mode bound keeps its exact constant

The dispersion expression for the finite circle is $\lambda_h(w) = 4h^{-2}\sin^2(wh/2)$. The source first proves

$$0 \leq x^2 - \sin^2 x \leq \frac{x^4}{3}$$

for every real x, using the quadratic upper bound for sine squared, the cubic error bound for $x - \sin x$ and the estimate $|x + \sin x| \leq 2|x|$. Substituting $x = wh/2$ yields

$$0 \leq w^2 - \lambda_h(w) \leq \frac{w^4}{12}h^2.$$

Source: formalization/LowModeConvergence.lean.

Exact lines 32 to 45. Excerpt low_mode. Hash in Section 12.

```
theorem low_mode_error (w h : ℝ) (hh : h≠0) :
    0 ≤ w^2-eigenvalue w h ∧ w^2-eigenvalue w h ≤ w^4/12*h^2 := by
  have hs := sine_square_error (w*h/2)
  have hpos : 0 ≤ 4/h^2 := by positivity
  have he : w^2-eigenvalue w h=4/h^2*((w*h/2)^2-Real.sin (w*h/2)^2) := by
    unfold eigenvalue
    field_simp
    ring
  rw [he]
  constructor
  · exact mul_nonneg hpos hs.1
  · calc
      _ ≤ 4/h^2*((w*h/2)^4/3) := mul_le_mul_of_nonneg_left hs.2 hpos
      _ = w^4/12*h^2 := by field_simp; ring
```

Proof reading. The proof scales the sine inequality by the nonnegative quantity $4/h^2$. A field calculation identifies the scaled error with $w^2 - \lambda_h(w)$. The final algebra simplifies its upper bound to the coefficient $1/12$. The hypothesis that the spacing is nonzero justifies division. The conclusion holds for every real w, without a restriction to small frequencies.

For a fixed frequency, the right-hand side tends to zero quadratically as h tends to zero through nonzero values. A growing frequency range needs control of w^4h^2. The theorem by itself does not prove convergence of an entire spectrum, a plateau in spectral dimension, a dynamics limit or a spacetime reconstruction. Those applications require their own quantified range and analytic arguments.

7.4 A compressed anomaly can vanish for purely algebraic reasons

The constraint audit sits beside the 19 finite ledger items. If every constraint annihilates P on the right, then every product term in the proposed anomaly also annihilates P on the right, so $P\mathcal{A}P = 0$ for arbitrary structure coefficients. The source needs no projector axioms for this observation.

Source: `formalization/ConstraintAudit.lean`.

Exact lines 31 to 34. Excerpt `constraint_kernel`. Hash in Section 12.

```
theorem compressed_anomaly_zero (C : I → R) (f : I → R)
    (P : R) (hP : ∀ c, C c * P = 0) (a b : I) :
    P * anomaly C f a b * P = 0 := by
  rw [mul_assoc, anomaly_annihilates_common_kernel C f P hP, mul_zero]
```

It also constructs a nonzero physical projector and two rational 3×3 constraints that act on its complement. Their commutator is nonzero, yet its physical compression is zero.

Source: `formalization/ConstraintAudit.lean`.

Exact lines 56 to 60. Excerpt `constraint_nonclosure`. Hash in Section 12.

```
theorem commutator_nonzero : constraintX * constraintZ - constraintZ * constraintX ≠ 0 := by
  intro h
  have h12 := congrArg (fun A : Matrix (Fin 3) (Fin 3) ℚ => A 1 2) h
  norm_num [constraintX, constraintZ, Matrix.mul_apply, Fin.sum_univ_succ] at h12
  norm_num [Matrix.cons_val_two] at h12
```

This supplies a concrete scope warning: exact compression to a common kernel cannot by itself certify operator closure on the whole space. It does not prove that an intended continuum constraint algebra exists or that every refinement has the same behavior. The hypotheses of the finite audit must be checked before applying it to a proposed physical construction.

7.5 The broader manuscript and the five open targets

Parts I and II discuss memory, geometry, diagnostics and physical interpretation beyond the named finite endpoints. A traditional proof can be more explanatory than a formal theorem statement, and a strengthened mathematical statement can go beyond the selected formal endpoint. Coverage is assigned by the full result map, not by similarity of wording or proximity on a page.

The original manuscript names five continuum conjectures: refinement without anomalies, uniform Feshbach control, Lorentzian reconstruction, an Einstein infrared limit and a massless sector with spin

two. None is a theorem target among the 19 ledger items. Finite path reconstruction, finite recovery, a projected connection, a resolvent identity and a dispersion error bound do not jointly prove those existence and limiting claims. The formal source provides rigorous finite ingredients and, in the geometric case, a broad calculus on parameter manifolds under its stated assumptions.

The complete theorem catalog includes seven declarations from the constraint audit, four Schur–Feshbach declarations and the other supporting lemmas. The count 323 therefore means named declarations in the current finite development, not 323 independently stated claims in the traditional paper, and not 323 continuum results.

9 Complete map of finite results

The following map reproduces all 19 ledger scope statements verbatim and resolves their current formal endpoints. Their recorded completion is supported by the saved compiler record under the stated hypotheses. It does not assert that every sentence in the traditional paper is separately formalized. Source pointers added where the ledger gives only a module are identified explicitly.

9.1 2.1 / Orbit dimension of one quantum seed

Preserved ledger scope. Actual matrix multiplication orbit, explicit equivalence with independently chosen rows, d times rank(C), and full-rank cyclicity when d is nonempty. No orbit-dimension hypothesis is assumed.

Formal endpoints.

- `KomorebiPaperVII.SeedOrbit.span_orbit_dimension`, `SeedOrbit.lean`, line 68.

9.2 2.2 / Quantum seed-rank formula

Preserved ledger scope. Actual sums of k matrix actions, full-column-rank seed construction, simultaneous finite direct-sum generation, and an IsLeast proof for max_i ceil(m_i/d_i). Every d_i is positive. Empty block families use supremum 0.

Formal endpoints.

- `KomorebiPaperVII.SeedOrbit.quantum_seed_rank`, `SeedOrbit.lean`, line 239.

9.3 2.3 / Local orbit and Schmidt rank

Preserved ledger scope. Actual Kronecker local action in standard product coordinates. Schmidt rank is independently defined as minimum product-vector decomposition length, with its equality to matrix rank proved. Derives local orbit dimension and equivalence with full support of the actual B-reduced matrix; the full-orbit equivalence assumes a nonempty A index.

Formal endpoints.

- `KomorebiPaperVII.SeedOrbit.local_orbit_reduced_support`, `SeedOrbit.lean`, line 364.

9.4 2.4 / One seed for the computational basis

Preserved ledger scope. Explicit local Pauli X addressing for every n, including n=0. The constructed gate word sends the zero seed to the standard coordinate basis, with linear independence, span and cardinality 2^n.

Formal endpoints.

- `KomorebiPaperVII.ComputationalSeed.circuit_seed_basis`, `ComputationalSeed.lean`, line 80.

9.5 3.1 / Cyclic quantum projectors

Preserved ledger scope. Constructs the primitive complex character and rho(r)=S^val(r) from S^N=1 for every N>0, including N=1. Proves exact exponential-root coefficient formula, character orthogonality, multiplication, completeness, eigenaction, and self-adjointness for unitary S. Includes a concrete complex-matrix theorem.

Formal endpoints.

- `KomorebiPaperVII.CyclicProjectors.finite_cyclic_projectors`, `CyclicProjectors.lean`, line 157.

9.6 3.2 / Tensor/polyphase refinement

Preserved ledger scope. Arbitrary finite tensor factors and dimensions. Proves tensor product multiplication, identity, adjoint and sum laws, then orthogonality, completeness and self-adjointness after grouping by total residue for N>0.

Formal endpoints.

- `KomorebiPaperVII.TensorRefinement.tensor_polyphase_refinement`, `TensorRefinement.lean`, line 139.

9.7 4.1 / Exact circuit path expansion

Preserved ledger scope. Arbitrary finite gate list, corner expansion and complete reconstruction.

Source pointers added by the guide.

- `KomorebiPaperVII.PacketFamily.circuit_path_expansion`, `QuantumPacketCore.lean`, line 63.
- `KomorebiPaperVII.PacketFamily.circuit_reconstruction`, `QuantumPacketCore.lean`, line 70.

9.8 4.2 / Packetwise unitarity conservation

Preserved ledger scope. Both identities in a star ring, plus concrete complex-matrix specializations.

Source pointers added by the guide.

- `KomorebiPaperVII.PacketFamily.unitarity_columns`, `QuantumPacketCore.lean`, line 119.
- `KomorebiPaperVII.PacketFamily.unitarity_rows`, `QuantumPacketCore.lean`, line 134.
- `KomorebiPaperVII.matrix_unitarity_columns`, `QuantumPacketCore.lean`, line 181.
- `KomorebiPaperVII.matrix_unitarity_rows`, `QuantumPacketCore.lean`, line 188.

9.9 5.1 / Exact symmetry packets

Preserved ledger scope. Generator blocks and actual exponential; zero cross-packet transfer.

Source pointers added by the guide.

- `KomorebiPaperVII.PacketFamily.symmetry_exponential_no_transfer`, `QuantumPacketCore.lean`, line 168.
- `KomorebiPaperVII.PacketFamily.symmetry_exponential_diagonal`, `QuantumPacketCore.lean`, line 163.

9.10 5.2 / Commutator leakage bound

Preserved ledger scope. Actual exponential with self-adjoint H and orthogonal P. Proves the Hilbert operator-norm bound for all real times, without nonzero-rank or nonempty-matrix assumptions. Also proves observable-conjugation Lipschitz continuity, the cap at one, and a symmetry-breaking perturbation estimate.

Formal endpoints.

- `KomorebiPaperVII.Leakage.matrix_commutator_leakage_bound`, `LeakageBound.lean`, line 167.

9.11 6.1 / Moving-frame Hamiltonian

Preserved ledger scope. Entrywise actual real derivatives of finite complex matrices and vectors. Constructs y=U*psi and its derivative, verifies the transformed Schrodinger equation and Hermiticity. The effective-Hamiltonian Hermiticity conclusion explicitly assumes H*=H.

Formal endpoints.

- `KomorebiPaperVII.MovingFrames.moving_frame_coordinates`, `MovingFrames.lean`, line 110.

9.12 6.3 / Canonical packet connection

Preserved ledger scope. Actual derivatives in a normed real star algebra with continuous star. Differentiates projector multiplication, completeness and self-adjointness to prove both formulas for C, skew-adjointness and [C,P_b]=dot(P_b). Does not include manifold curvature.

Formal endpoints.

- `KomorebiPaperVII.Connection.canonical_connection_of_hasDerivAt`, `CanonicalConnection.lean`, line 113.

9.13 6.4 / Projected connection

Preserved ledger scope. Smooth real boundaryless parameter manifolds modeled on a complete normed space; complete real normed fibers, including finite quantum spaces through underlying real calculus. Constructs the actual range total space, open local product homeomorphisms, smooth fiber-linear transitions, inverse and cocycle laws, and locally constant rank. Proves local smooth-section equivalence, the actual global covariant derivative, connection laws and gauge gluing. Derives curvature using actual manifold derivatives and the actual Lie bracket, and proves tensoriality. Uses an explicit smooth atlas rather than a packaged Mathlib ContMDiffVectorBundle instance. No global chart, pre-existing range-bundle atlas or curvature identity is assumed.

Formal endpoints.

- `KomorebiPaperVII.ManifoldCurvature.projected_connection_curvature`, `ManifoldProjectedCurvature.lean`, line 214.
- `KomorebiPaperVII.RangeBundle.smooth_range_bundle_atlas`, `GlobalRangeBundle.lean`, line 241.
- `KomorebiPaperVII.BundleCompletion.localProduct_overlap`, `ProjectedBundleCompletion.lean`, line 31.
- `KomorebiPaperVII.BundleCompletion.smooth_section_iff`, `ProjectedBundleCompletion.lean`, line 40.

- `KomorebiPaperVII.GlobalConnection.covariant`, `GlobalProjectedConnection.lean`, line 44.
- `KomorebiPaperVII.GlobalConnection.local_connections_glue`, `GlobalProjectedConnection.lean`, line 115.
- `KomorebiPaperVII.BundleCompletion.local_connections_gauge`, `ProjectedBundleCompletion.lean`, line 57.

9.14 7.1 / Block-diagonal measurement invariance

Preserved ledger scope. Trace duality, measurement invariance and trace preservation for finite complex matrices.

Source pointers added by the guide.

- `KomorebiPaperVII.measurement_invariance`, `QuantumPacketCore.lean`, line 208.
- `KomorebiPaperVII.dephase_trace_preserving`, `QuantumPacketCore.lean`, line 213.

9.15 7.2 / Finite Kraus channel

Preserved ledger scope. Finite complex matrix Kraus map: linearity, positivity, trace preservation under sum(K* K)=I, identity-tensor amplification at every finite auxiliary dimension, complete positivity and density-matrix preservation.

Formal endpoints.

- `KomorebiPaperVII.Kraus.channel_completely_positive`, `KrausChannels.lean`, line 58.

9.16 8.1 / Finite Knill-Laflamme criterion

Preserved ledger scope. Full finite complex-matrix Knill-Laflamme criterion. Constructs a total completely positive trace-preserving recovery from general positive semidefinite Gram data using actual spectral diagonalization, positive-eigenvalue support and proof that null errors vanish. Derives necessity from actual recovery via rank-one Kraus rigidity. Proves equivalence for normalized code density matrices, preservation with arbitrary finite references, the unnormalized error-family criterion with an explicit nonnegative scale, and correction of every normalized channel in the same error span by the same recovery. Zero code is handled separately. This is a mathematical, noncomputable spectral construction, not a numerical decoder implementation.

Formal endpoints.

- `KomorebiPaperVII.KnillLaflamme.state_correctable_iff_gram`, `QuantumStateBridge.lean`, line 139.
- `KomorebiPaperVII.KnillLaflamme.error_family_correctable_iff_gram`, `ErrorSpanRecovery.lean`, line 188.
- `KomorebiPaperVII.KnillLaflamme.Data.recovery_span_channel`, `ErrorSpanRecovery.lean`, line 138.
- `KomorebiPaperVII.KnillLaflamme.recovery_with_reference`, `QuantumStateBridge.lean`, line 164.

9.17 9.1 / Exact Feshbach resolvent

Preserved ledger scope. Corrected: eliminated block AND full resolvent matrix invertible. Paper VI proof reused.

Source pointers added by the guide.

- `KomorebiPaperVII.SchurFeshbach.projected_resolvent`, `SchurFeshbach.lean`, line 27.
- `KomorebiPaperVII.SchurFeshbach.schur_invertible`, `SchurFeshbach.lean`, line 46.

9.18 10.1 / Finite Euclidean transfer

Preserved ledger scope. Actual power-series matrix exponential, identified with continuous functional calculus. Constructs the minimum eigenvalue on a nonempty finite state space, proves positive definiteness, semigroup composition, and real and complex spectrum containment in (0,1] for nonnegative time.

Formal endpoints.

- `KomorebiPaperVII.EuclideanTransfer.finite_euclidean_transfer`, `EuclideanTransfer.lean`, line 89.

9.19 11.1 / Low-mode second-order bound

Preserved ledger scope. Explicit h != 0; stronger all-real-frequency bound with constant 1/12. Paper VI proof reused.

Source pointers added by the guide.

- `KomorebiPaperVII.LowModeConvergence.low_mode_error`, `LowModeConvergence.lean`, line 32.

10 All named theorem declarations

The following catalog is derived from active declarations in the 25 current source modules, with nested namespaces resolved. It is reconciled against the saved theorem inventory and all 323 saved axiom reports. It includes supporting lemmas, the finite constraint audit, and strengthened endpoints. The count therefore describes formal declarations rather than 323 separate manuscript theorems. The source line identifies the declaration. "Core" marks an endpoint in the map of finite results, while "support" marks a declaration used in the formal development or its scope audit. All saved axiom sets lie within `propext`, `Classical.choice`, and `Quot.sound`. The complete sets accompany the guide with their source identities.

11 Module dependencies, source identities, and pins

11.1 Current local module graph

The dependencies below are read from public imports and commands of the form import all. Duplicate imports count once. Importing all declarations matters in this Lean source because downstream proofs can require private implementation details. A module with no local import still imports the pinned Mathlib files named in its source.

Module	Direct current local imports
`CanonicalConnection`	Mathlib only
`ComputationalSeed`	Mathlib only
`ConstraintAudit`	Mathlib only
`CyclicProjectors`	Mathlib only
`ErrorSpanRecovery`	`KnillLaflammeNecessity`, `KnillLaflammeSufficiency`, `QuantumStateBridge`, `SyndromeRecovery`
`EuclideanTransfer`	Mathlib only
`GlobalProjectedConnection`	`GlobalRangeBundle`, `LocalProjectedCurvature`, `ProjectedCurvature`
`GlobalRangeBundle`	Mathlib only

12 Exact excerpt register

Each excerpt is a contiguous block of the unchanged source, retaining its full declaration and proof. The printed code uses explicit font fallback only where the monospaced font lacks a glyph. The corresponding `.lean.txt` file preserves raw UTF-8, without editorial substitutions. The source and excerpt hashes below bind the printed selection to its original context. The assumptions declared in a module remain in force when an excerpt is read. The teaching chapters state the relevant type classes and hypotheses.

row_equiv

Source: `formalization/SeedOrbit.lean`.

Lines 45 to 52. Declaration `orbitRowEquiv`.

Source SHA-256: `0b1da8c7e74ccc7bbca8e2b7c0c26bce01bc95d4089616ba95c1e4fe2f147773`.

Packet Operator Algorithms

The formal companion to Chapter VIII explains the declared hypotheses, theorem correspondences and evidence boundaries.

IN THIS COMPANION

Formal companion 2133

Return to Chapter VIII

How to use this volume

This guide teaches the actual finite Lean development. It follows the represented objects, states their hypotheses, and reads representative proofs step by step. It includes 61 exact source selections, the complete 56-result correspondence, four separately tracked classical inputs, and all 458 named audit entries.

The source has 40 modules, 392 theorem declarations (373 for Chapter VIII and 19 in the reused foundation), and 66 construction audits. These counts include supporting results and specializations. They do not count independent mathematical discoveries.

Three broader research targets remain open: unrestricted discovery of profitable packet structure, compilation with nonlocal costs and overlapping decompositions, and a packet memory communication theorem for a specified architecture.

The recorded formal run contains successful cumulative compilation and axiom audits. Source identities, saved logs, declaration names and exact excerpts identify the scope of that evidence. The reproduction section supplies the toolchain and replay procedure. This reading guide does not claim a new kernel execution.

The traditional paper develops the mathematical arguments. The visual guide works through their constructions. This companion explains their formal counterparts and the exact boundary between proved conclusions and supplied data. The accompanying `README.md` gives the complete monograph regeneration sequence, including static evidence refresh and final page navigation before rebuilding.

Source base: `original_snapshot/formalization/`.

Primary inherited evidence: `original_snapshot/verification/sixth_final/`.

Raw UTF-8 excerpts and their SHA-256 register accompany the printed selections.

1 Reading a finite formal development

1.1 The objects precede the theorem names

A packet representation starts with a finite projector family and an operator. A structured representation adds explicit factor matrices or tensor coordinates. A compiler starts with a finite candidate tree and an independently defined set of legal cuts. An error theorem starts with actual errors in a normed space and budgets that bound them. In each case, the theorem follows the object being modeled. Reading only the endpoint name misses the domain, norm, convention, and supplied data on which its conclusion depends.

Use the traditional paper's original item numbers to find the corresponding subsection in Section 12. Then locate its declaration in Section 13 and its module in Section 14. For a first reading, work through the chapters in order. The small-core chapter is longer because the final block proves optimality from several independent ingredients, rather than accepting an optimality certificate as input.

1.2 A short Lean vocabulary

Source form	Meaning in this guide
`Matrix m n K`	A function with row type `m`, column type `n`, and coefficients in `K`. Finite index instances provide finite sums. Rectangular shapes are visible in the type.
`[Fintype I]`	A finite enumeration of the index type. Empty index types are allowed unless a nonempty hypothesis is separately stated.
`[DecidableEq I]`	Equality can be decided where the construction needs it. It is not a numerical tolerance test.
`Fin k`	Natural indices smaller than k. The type `Fin 0` is empty.
`[Ring R]`	Addition and multiplication are available, but multiplication need not commute.
`IsUnit D`	The matrix or algebra element has a two-sided multiplicative inverse. A displayed inverse expression alone does not establish invertibility.
`X →L[K] X`	A continuous linear map over `K`, with its operator norm.
`Option R`	Either `some v`, a finite candidate value, or `none`, an unreachable / infeasible state.
`let A := ...`	A local definition in the statement. It abbreviates the constructed object. It adds no hypothesis.
`noncomputable def`	A mathematically defined object using classical choice or other noncomputable ingredients. It does not advertise an executable numerical routine.

A theorem statement may inherit `variable` declarations from its section. An `omit ... in` command removes unused instances for that declaration. `autoImplicit false` means an undeclared symbol is rejected rather than silently turned into an implicit parameter. Names such as `SmallCore.spectralNorm` explicitly choose the intended norm. A bare matrix norm also depends on the open norm scope surrounding its declaration.

1.3 How to read a proof

`rw` rewrites by an equality. `simp` applies named simplification facts, while `simp only` restricts that collection. `funext` reduces equality of functions to equality at an arbitrary argument, while `ext` exposes entries of a structured object. `refine` supplies a proof expression with remaining holes. `have` names an intermediate proposition and its proof. `exact` closes a goal with a term of the required type.

Induction is visible in the recursive structured algorithms and dynamic programs. A `calc` chain shows the successive equalities or inequalities used in a norm estimate. Arithmetic tactics have limited roles: `ring` normalizes polynomial identities, `omega` handles integer and natural-number constraints, and `linarith`/`nlinarith` combine supplied real inequalities. They do not supply unrecorded analytic or hardware assumptions.

1.4 Which evidence is current

The inherited sixth-block report records the compiler, source hashes, local dependency hashes, saved log hashes, axiom sets, and two rejected invalid-proof controls. The present guide replays the static identity checks on those retained bytes. It does not reconstruct compiled interfaces or simulate a Lean invocation. The exact distinction is preserved in `generated/documentation_reconciliation.json`.

The allowed transitive axiom policy is `propext`, `Classical.choice`, and `Quot.sound`, or subsets of them. This is the policy accepted by the recorded run. A passing audit excludes an admitted-proof axiom under that policy. It does not independently rebuild all imported Mathlib proofs. Manuscript correspondence remains mathematical review.

2 Navigation through the traditional volume

The Printed and PDF columns locate results in the attached Chapter VIII source document. Physical PDF pages include its cover and opening material. These locations refer to that source document rather than the continuous folios of this book. Original result numbers remain the correspondence keys.

2.1 All 56 registered finite results

The page map locates each manuscript statement. The formal hypotheses in Section 12 describe its actual finite counterpart. These page locations do not expand the formal contract.

11.3	11.3	Fair matching is an equivalence relation	36	42

2.2 The four separately supplied classical inputs

These inputs are tracked separately from the 56 finite results. Their exact boundaries are discussed in the replay chapter.

Item	Number	Classical input	Printed	PDF
5.5	5.5	Eckart Young Mirsky theorem	18	24
7.5	7.5	Preconditioned conjugate gradient convergence	25	31
8.2	8.2	Floating point matrix product model	27	33
9.1	9.1	Simultaneous spectral decomposition	30	36

2.3 The open research boundary

The traditional boundary discussion is on printed page 42 (PDF page 48). It retains the three broader targets: discovery of profitable structure for arbitrary operators, controlled compilation for overlapping decompositions and nonlocal costs, and a communication theorem for a specified packet memory architecture. Their finite special cases do not settle those broader targets.

3 Exact packet semantics

3.1 The reused projector family

The unchanged `QuantumPacketCore` foundation uses a ring `R` and finite packet type `I`. The projectors multiply orthogonally and sum to one. Their block $P_b A P_a$ uses the target index first. This algebraic model already covers noncommutative operator multiplication.

Source: `formalization/QuantumPacketCore.lean`.

Exact lines 22–25. Excerpt `packet_family`. SHA-256 in Section 15.

```
structure PacketFamily (R I : Type*) [Ring R] [Fintype I] [DecidableEq I] where
  proj : I → R
  mul_proj : ∀ i j, proj i * proj j = if i = j then proj i else 0
  sum_proj : ∑ i, proj i = 1
```

Proof reading. The structure fields are assumptions defining a packet family. Idempotence is derived by setting the two indices equal, and reconstruction follows by expanding the two sums of projectors. A finite projector family is supplied to later theorems, so discovery of an appropriate family is a separate mathematical or application task.

3.2 Deleting exact zero blocks

`activeBlocks P A` filters the finite set of ordered packet pairs by the predicate that the actual block is unequal to zero. `evalActive` sums only those surviving blocks.

Source: `formalization/PacketIR.lean`.

Exact lines 41–49. Excerpt `active_evaluation`. SHA-256 in Section 15.

```
theorem exact_active_evaluation (A : R) : evalActive P A = A := by
  classical
  have term (e : I × I) :
      (if P.block A e.1 e.2 ≠ 0 then P.block A e.1 e.2 else 0) =
      P.block A e.1 e.2 := by
    by_cases h : P.block A e.1 e.2 = 0 <;> simp [h]
  simp only [evalActive, activeBlocks, Finset.sum_filter]
  simp_rw [term]
  simpa only [Fintype.sum_prod_type] using P.reconstruct A
```

Proof reading. The local lemma `term` checks two cases: a block equals zero or it does not. In either case, replacing it by an if-expression preserves the value. The proof expands the filtered sum, rewrites every term by this lemma, and applies the foundation's reconstruction theorem. No thresholded support is used.

Source: `formalization/PacketIR.lean`.

Exact lines 145–149. Excerpt `batch`. SHA-256 in Section 15.

```
theorem exact_matrix_batch {C : Type*} (P : PacketFamily (Matrix X X K) I)
    (A : Matrix X X K) (Z : Matrix X C K) :
```

```
    A * Z = ∑ e ∈ activeBlocks P A, (P.block A e.1 e.2) * Z := by
  rw [← Matrix.sum_mul]
  exact congrArg (fun a : Matrix X X K => a * Z) (exact_active_evaluation P A).symm
```

Proof reading. A rectangular right-hand-side matrix `Z` may have any column type `C`. Distribution of matrix multiplication over the finite sum turns exact operator reconstruction into equality of the whole output batch. The result concerns actual matrix multiplication, rather than a Boolean sparsity specification.

3.3 Support composition and cancellation

Source: `formalization/PacketIR.lean`.

Exact lines 63–77. Excerpt `support_inclusion`. SHA-256 in Section 15.

```
theorem product_support_inclusion (A B : R) (b a : I)
    (h : P.block (A * B) b a ≠ 0) :
    ∃ c, P.block A b c ≠ 0 ∧ P.block B c a ≠ 0 := by
  classical
  by_contra no
  apply h
  rw [P.compose_blocks]
  apply Finset.sum_eq_zero
  intro c _
  by_cases hc : P.block A b c = 0
  · simp [hc]
  · have hd : P.block B c a = 0 := by
      by_contra hd
      exact no ⟨c, hc, hd⟩
    simp [hd]
```

Proof reading. The premise says the product block is nonzero. Assume no intermediate packet has both nonzero constituent blocks. For each intermediate index, either the first block is zero or the assumption forces the second to be zero. Every summand in the composition formula vanishes, contradicting the premise. This proves an inclusion of support relations. It supplies no converse: nonzero paths can cancel. The separate `BoundaryChecks.paths_can_cancel` declaration records a concrete control.

3.4 An adjoint needs the right projector hypothesis

Source: `formalization/PacketIR.lean`.

Exact lines 95–97. Excerpt `adjoint`. SHA-256 in Section 15.

```
theorem exact_adjoint_block (A : R) (b a : I) :
    star (P.block A b a) = P.block (star A) a b :=
  P.adjoint_block hstar A b a
```

Contract. The surrounding section has a star ring and an explicit `hstar : ∀ a, star (P.proj a) = P.proj a`.

Proof reading. The source calls the foundation's adjoint identity with that self-adjointness proof. Adjoint reversal swaps target and source. Orthogonal idempotence in an arbitrary ring alone does not establish self-adjointness. Tensor semantics are separately proved with actual Kronecker products. Their address types are pairs of packet indices.

3.5 The Python prototype is a different object

The supplied Python prototype's support accessor returns stored block keys, which may include explicitly stored zeros. The formal `activeBlocks` set instead tests exact nonzero matrix blocks. The two objects agree only when the stored representation has already removed all zero blocks and realizes the same matrices. No automatic equivalence between the prototype and the Lean representation is asserted here.

4 Representation algebra and declared cost models

4.1 Why a count theorem can have a short proof

`PacketCostModels` defines finite address and event types before counting them. The block widths are natural numbers. A diagonal block has a pair of within-block indices. A thin factor has one ambient and one rank index. An application event additionally has a right-hand-side index and a Boolean distinguishing multiplication from accumulation. The Boolean gives the declared two-scalar-operation convention.

Source: `formalization/PacketCostModels.lean`.

Exact lines 68–73. Excerpt `bdlr_count`. SHA-256 in Section 15.

```
theorem bdlr_application_count {I : Type*} [Fintype I]
    (width : I → ℕ) (n r q : ℕ) :
    Fintype.card (BDLROperation I width n r q) =
      2 * q * ((∑ i, width i ^ 2) + 2 * n * r) := by
  simp [BDLROperation, pow_two]
  ring
```

Proof reading. The type `BDLROperation` is a sum of the diagonal-action, right-factor, and left-factor event types. `simp` evaluates cardinalities of finite products and sums, and `ring` rearranges the resulting polynomial. The count includes the accumulation into the diagonal result through the declared third kernel. It does not establish how many GPU instructions run.

The storage count concerns stored scalar values. Sparse index metadata and workspace are outside the corresponding models. The materialization theorem counts an explicit dense low-rank multiplication followed by one addition per output entry. Its quadratic remainder is exactly n^2. This is a count for that declared construction, rather than a lower bound for every conceivable implementation.

Source: `formalization/BandedCount.lean`.

Exact lines 73–77. Excerpt `band_count`. SHA-256 in Section 15.

```
theorem banded_block_count (p w : ℕ) (hw : w < p) :
    Fintype.card (BandedAddress p w) = p*(2*w+1)-w*(w+1) := by
  rw [bandCount_card]
  have he := bandCount_balance p w hw
  omega
```

Proof reading. The banded-count development counts the actual subtype of pairs in `Fin p × Fin p` whose distance is at most `w`. The premise `w < p` controls the two triangular boundary losses. The preceding recurrence and finite-sum lemmas establish the cardinality. This endpoint presents the closed formula. Replacing p by n/b additionally requires positive block width and exact divisibility.

4.2 Capacity inequalities are hypotheses

Source: `formalization/PacketCostModels.lean`.

Exact lines 118–124. Excerpt `roofline`. SHA-256 in Section 15.

```
theorem roofline_time_bound (F B P W T : ℝ) (hP : 0 < P) (hW : 0 < W)
    (hF : F ≤ P * T) (hB : B ≤ W * T) : max (F / P) (B / W) ≤ T := by
  apply max_le
  · apply (div_le_iff₀ hP).2
    nlinarith
  · apply (div_le_iff₀ hW).2
    nlinarith
```

Proof reading. Positive peak arithmetic and bandwidth rates make division preserve order. The assumed inequalities `F ≤ P * T` and `B ≤ W * T` yield the two lower bounds on time, then `max_le` combines them. Lean does not measure a device rate or validate that an experimental execution satisfies these capacity assumptions.

4.3 An exact low-rank product

Contract. `LowRankAlgebra` works with actual finite matrices over a field with an involution. The left and right factors have explicit possibly different width types.

Source: `formalization/LowRankAlgebra.lean`.

Exact lines 57–65. Excerpt `bdlr_product`. SHA-256 in Section 15.

```
theorem bdlr_product (DA DB : Matrix X X K) (UA VA : Matrix X RA K)
    (UB VB : Matrix X RB K) :
    (DA + UA * VA.conjTranspose) * (DB + UB * VB.conjTranspose) =
      DA * DB + bdlrProductLeft DA UA VA UB * (bdlrProductRight DB VA VB).conjTranspose := by
  simp only [bdlrProductLeft, bdlrProductRight,
    Matrix.conjTranspose_fromCols_eq_fromRows_conjTranspose,
    Matrix.fromCols_mul_fromRows, Matrix.conjTranspose_mul, Matrix.conjTranspose_conjTranspose,
    Matrix.add_mul, Matrix.mul_add, Matrix.mul_assoc]
  abel
```

Proof reading. The constructors `bdlrProductLeft` and `bdlrProductRight` concatenate columns, so the new correction width is the sum of the two input widths. The proof expands the concatenated product, reverses conjugate transposes of products, distributes multiplication, and normalizes additive terms. No rank identity is assumed in this algebraic equality. A separate theorem bounds the correction rank by its column count. Packet diagonality of the base product is also proved separately.

Source: `formalization/LowRankChains.lean`.

Exact lines 56–66. Excerpt `chain_factors`. SHA-256 in Section 15.

```
theorem chainFactors_correct (n : ℕ) :
    chainProduct (fun j => D j + U j * (V j).conjTranspose) n =
      chainProduct D n + (chainFactors r D U V n).1 * (chainFactors r D U V n).2.conjTranspose :=
      ↪ by
```

```
  induction n with
  | zero =>
    ext i j
    simp [chainProduct, chainFactors, ChainColumns]
  | succ n ih =>
    rw [chainProduct, ih]
    exact bdlr_product (D n) (chainProduct D n) (U n) (V n)
      (chainFactors r D U V n).1 (chainFactors r D U V n).2
```

Proof reading. The empty chain is the identity and has an empty correction-column type. For the successor step, rewrite the current chain using the induction hypothesis and invoke the actual two-factor identity. The source thereby constructs factors for every length. The subsequent rank theorem bounds their width by the sum of input widths, including zero widths.

4.4 Woodbury exposes both invertibility assumptions

Source: `formalization/LowRankAlgebra.lean`.

Exact lines 89–94. Excerpt `woodbury`. SHA-256 in Section 15.

```
theorem bdlr_woodbury (D : Matrix X X K) (U V : Matrix X Rk K)
    (hD : IsUnit D) (hS : IsUnit (1 + V.conjTranspose * D⁻¹ * U)) :
    (D + U * V.conjTranspose)⁻¹ =
      D⁻¹ - D⁻¹ * U * (1 + V.conjTranspose * D⁻¹ * U)⁻¹ * V.conjTranspose * D⁻¹ := by
  simpa using Matrix.add_mul_mul_inv_eq_sub D U (1 : Matrix Rk Rk K)
    V.conjTranspose hD isUnit_one (by simpa using hS)
```

Proof reading. `hD` proves the base matrix is a unit. `hS` proves the small update matrix is a unit. The endpoint specializes Mathlib's Woodbury identity, with the middle rank-space matrix equal to one. The update's invertibility, batch solve formula, and L2 operator norm bound are independent declarations in the same module. A singular base or singular update matrix cannot be passed through the displayed theorem simply because an inverse notation exists.

5 Structured algorithms carry their coordinate conventions

5.1 Vectorization and recursive tensor contraction

Source: `formalization/StructuredTensor.lean`.

Exact lines 19–22. Excerpt `kronecker`. SHA-256 in Section 15.

```
theorem kronecker_modewise {M N : Type*} [Fintype M] [Fintype N]
    (A : Matrix M M ℂ) (B : Matrix N N ℂ) (X : Matrix N M ℂ) :
    (A ⊗ₖ B) *ᵥ Matrix.vec X = Matrix.vec (B * X * Aᵀ) := by
  exact Matrix.kronecker_mulVec_vec B X A
```

Proof reading. The right factor in the matrix expression is $\mathtt{A}^{\mathrm{T}}$, the ordinary transpose. It is not the conjugate transpose. The argument order reflects Mathlib's column-major `Matrix.vec` convention: $(A \otimes B)\,\mathrm{vec}(X) = \mathrm{vec}(BXA^{T})$. The one-line proof invokes that exact library identity.

`TensorIndex d 0` is `Unit`, and the successor index is `Fin d × TensorIndex d k`. This makes the tensor dimension d^{k} visible without an implicit flattening convention. `tensorMatrix` builds iterated actual Kronecker matrices. `tensorApply` contracts trailing slices before the first mode.

Source: `formalization/StructuredTensor.lean`.

Exact lines 73–96. Excerpt `tensor_apply`. SHA-256 in Section 15.

```
theorem tensor_apply_correct (d k : ℕ) (A : Fin k → Matrix (Fin d) (Fin d) ℂ)
    (x : TensorIndex d k → ℂ) :
    tensorApply d k A x = tensorMatrix d k A *ᵥ x := by
  induction k with
  | zero =>
    funext i
    cases i
    change x PUnit.unit = ∑ i : Unit, (1 : ℂ) * x i
    simp only [one_mul]
    symm
    apply Finset.sum_eq_single PUnit.unit
    · intro b _ h
      cases b
      exact (h rfl).elim
    · intro h
      exact (h (Finset.mem_univ _)).elim
  | succ k ih =>
    funext p
    change (∑ j, A 0 p.1 j * tensorApply d k (fun i => A i.succ) (fun u => x (j,u)) p.2) = _
    simp_rw [ih]
    change (∑ j, A 0 p.1 j * (∑ u, tensorMatrix d k (fun i => A i.succ) p.2 u * x (j,u))) =
      ∑ i : Fin d × TensorIndex d k,
        (A 0 p.1 i.1 * tensorMatrix d k (fun j => A j.succ) p.2 i.2) * x i
    simp only [Fintype.sum_prod_type, Finset.mul_sum, mul_assoc]
```

Proof reading. The zero-mode case reduces to the one-coordinate identity. In the successor case, expand one contraction, rewrite trailing contractions using the induction hypothesis, and express the

full matrix sum over a product type as two nested sums. Associativity and distribution align the two formulas. The event type counted later follows this recursive contraction, yielding $2kd^{k+1}$ operations in the declared model and kd^2 factor values. Cases $k = 0$ and $d = 0$ are represented by their actual index types.

5.2 The Walsh butterfly proves an implemented recursion

Source: `formalization/WalshTransform.lean`.

Exact lines 60–84. Excerpt `walsh_apply`. SHA-256 in Section 15.

```
theorem walsh_apply_correct (k : ℕ) (x : TensorIndex 2 k → ℂ) :
    walshApply k x = walshMatrix k *ᵥ x := by
  induction k with
  | zero =>
    funext i
    cases i
    change x PUnit.unit = ∑ i : Unit, (1:ℂ)*x i
    simp only [one_mul]
    symm
    apply Finset.sum_eq_single PUnit.unit
    · intro b _ h
      cases b
      exact (h rfl).elim
    · intro h
      exact (h (Finset.mem_univ _)).elim
  | succ k ih =>
    funext p
    rcases p with ⟨i,u⟩
    change (if i = 0 then walshApply k (fun v => x (0,v)+x (1,v)) u
      else walshApply k (fun v => x (0,v)-x (1,v)) u) =
        ∑ v : Fin 2 × TensorIndex 2 k, (walshTwo i v.1 * walshMatrix k u v.2) * x v
    simp_rw [ih]
    fin_cases i <;>
      simp [walshTwo, Matrix.mulVec, dotProduct, Fintype.sum_prod_type,
        Fin.sum_univ_two, mul_add, Finset.sum_add_distrib, sub_eq_add_neg]
```

Proof reading. The recursively constructed `walshMatrix` matrix is paired with the actual sum/difference routine `walshApply`. The proof follows the same split of tensor coordinates and expands the two butterfly branches. Its equality states algorithm correctness. The separate operation theorem counts additions and subtractions, giving $N \log_2 N$ for $N = 2^k$, including $N = 1$. Orthogonality uses the ordinary transpose of these real-valued complex matrices.

5.3 Toeplitz padding is concrete

Contract. The matrix and generator definitions assume `[NeZero n]`, so the length is positive. The zero-padding helper itself is meaningful without that instance.

Source: `formalization/ToeplitzEmbedding.lean`.

Exact lines 54–58. Excerpt `toeplitz_apply`. SHA-256 in Section 15.

```
theorem toeplitz_embedding_action (c r x : Fin n → ℂ) (i : Fin n) :
    (Matrix.circulant (toeplitzGenerator c r) *ᵥ zeroPad x) (Fin.castAdd n i) =
      (toeplitzMatrix c r *ᵥ x) i := by
  simp only [Matrix.mulVec, dotProduct, Fin.sum_univ_add, zero_pad_left, zero_pad_right,
    mul_zero, Finset.sum_const_zero, add_zero, toeplitz_circulant_block]
```

Proof reading. The preceding theorem identifies the actual top-left Toeplitz block of the length-$n+n$ circulant. This application theorem expands the zero-padded vector with `Fin.addCases`. Terms in the right half vanish, leaving precisely the Toeplitz action. The generator reverses the row tail in its second half. Its first entry uses the column datum `c 0`, and `r 0` is irrelevant. No symmetry or Hermiticity is assumed.

5.4 Fourier diagonalization is exact, with no FFT timing claim

Source: `formalization/CirculantFourier.lean`.

Exact lines 150–153. Excerpt `fourier`. SHA-256 in Section 15.

```
theorem circulant_spectral_representation (c : ZMod n → ℂ) :
    Matrix.circulant c = (fourierMatrix n)ᴴ *
      Matrix.diagonal ((Real.sqrt (n:ℝ) : ℂ) • (fourierMatrix n *ᵥ c)) * fourierMatrix n := by
  rw [normalized_fourier_eigenvalues, circulant_spectral_dft]
```

Proof reading. For a positive length n, the module defines the actual circulant and the unitary-normalized Fourier matrix on `ZMod n`. The proof rewrites the DFT diagonalization using the normalization identities and actual Fourier unitarity. Supporting declarations establish the complex exponential entry formula, eigenvalues, and both unitarity products. The final application formula uses two transforms. This establishes the represented algebraic action. An FFT algorithm, its execution cost, and hardware timing remain distinct tasks.

6 Transfer paths, inverses, and acyclic solves

6.1 A path expansion covers length zero

Contract. `TransferSupport` uses a finite packet family in a ring. `TransferPath P A n b a` records a path of exactly n active edges, from source a to target b.

Source: `formalization/TransferSupport.lean`.

Exact lines 37–52. Excerpt `power_paths`. SHA-256 in Section 15.

```
theorem power_path_expansion (A : R) (n : ℕ) (b a : I) :
    P.block (A ^ n) b a = activePathSum P A n b a := by
  classical
  induction n generalizing b a with
  | zero =>
      by_cases h : b = a
      · subst b
        simp [activePathSum, PacketFamily.block, P.mul_proj]
      · simp [activePathSum, PacketFamily.block, P.mul_proj, h]
  | succ n ih =>
      rw [pow_succ', P.compose_blocks]
      simp only [activePathSum]
      apply Finset.sum_congr rfl
      intro c _
      rw [ih]
      by_cases h : P.block A b c = 0 <;> simp [h]
```

Proof reading. Induct on the exponent. At length zero, the identity block is a projector on the diagonal and zero off the diagonal. At a successor, use block composition and the induction hypothesis for each intermediate packet. A zero first edge contributes nothing, while a nonzero first edge extends a path. The result is an exact sum of path products, so cancellation still allows its support inclusion to be strict.

Source: `formalization/TransferSupport.lean`.

Exact lines 86–90. Excerpt `nilpotent`. SHA-256 in Section 15.

```
theorem nilpotent_of_path_bound (A : R) (h : ℕ)
    (hpaths : ∀ b a, ¬ TransferPath P A (h + 1) b a) : A ^ (h + 1) = 0 := by
  apply all_blocks_zero P
  intro b a
  exact power_block_zero_of_no_path P A (h + 1) b a (hpaths b a)
```

Proof reading. If no pair has a path of the stated length, every block of that power is zero. Reconstruction then forces the whole power to be zero. The level-based version derives a path bound from a supplied strict level function. It does not assume that nonzero paths always survive in the operator.

6.2 Inverse support uses finite dimensionality

Contract. The inverse-support module has a field `K`, a `K`-algebra `R`, and `FiniteDimensional K R`. It defines the subspace of elements with zero components at every packet unreachable from the starting packet. Reachability includes zero-length paths.

Source: `formalization/InverseSupport.lean`.

Exact lines 94–100. Excerpt `inverse_support`. SHA-256 in Section 15.

```
theorem inverse_block_zero_of_no_path (A B : R) (hBA : B*A = 1) (b a : I)
    (h : ¬ Reachable P A b a) : P.block B b a = 0 := by
  have hm := invariant_space_inverse (K := K) A B hBA
    (reachableSpace (K := K) P A a) (reachableSpace_invariant P A a)
    (P.proj a) (seed_mem_reachableSpace P A a)
  have hz := hm b h
  simpa only [PacketFamily.block,mul_assoc] using hz
```

Proof reading. The source first proves that the forward multiplication by `A` preserves the reachable subspace. A left inverse makes that restricted map injective, and finite dimensionality makes it surjective. The helper `invariant_space_inverse` therefore shows that multiplication by `B` preserves the same subspace. Apply it to the seed projector and read its unreachable component. The matrix specialization supplies the relevant inverse hypothesis from matrix invertibility. No inverse sparsity pattern is assumed.

6.3 Schur fill follows routes through eliminated packets

Source: `formalization/SchurSupport.lean`.

Exact lines 57–73. Excerpt `schur_support`. SHA-256 in Section 15.

```
theorem schur_support_inclusion (A : Matrix X X K) (B : Matrix X Y K)
    (H : Matrix Y Y K) (C : Matrix Y X K) (hH : IsUnit H.det) (b a : I)
    (h : P.block (A-B*H⁻¹*C) b a ≠ 0) :
    P.block A b a ≠ 0 ∨
      ∃ j k, P.proj b*B*Q.proj j ≠ 0 ∧ Reachable Q H j k ∧
        Q.proj k*C*P.proj a ≠ 0 := by
  by_cases ha : P.block A b a ≠ 0
  · exact Or.inl ha
  · right
    apply schur_correction_support P Q B H C hH b a
    intro hc
    apply h
    have hz : P.block A b a = 0 := not_ne_iff.mp ha
    change P.proj b*(A-B*H⁻¹*C)*P.proj a = 0
    rw [Matrix.mul_sub,Matrix.sub_mul]
    change P.block A b a - P.block (B*H⁻¹*C) b a = 0
    rw [hz,hc,sub_self]
```

Proof reading. The premise is a nonzero block of the actual Schur complement $A - BH^{-1}C$. If the original A-block is nonzero, the first alternative applies. Otherwise, the correction block must be

nonzero. Expand it through the eliminated packet family and use inverse support: a surviving term has an incoming block, a route through H, and an outgoing block. The determinant-unit premise establishes invertibility of H. The conclusion allows fill. It does not say every route creates a nonzero fill block.

6.4 The graph level is constructed

`DAG.Graph` contains a finite edge relation and the hypothesis that no vertex lies on a nonempty directed cycle. The source proves that the ancestor set strictly grows along an edge. Its finite cardinality gives a well-founded recursion. The resulting level is one plus the maximum predecessor level. Sources start at level one. The empty graph's maximum and depth are zero.

Source: `formalization/GraphSchedules.lean`.

Exact lines 150–154. Excerpt `schedule_depth`. SHA-256 in Section 15.

```
theorem optimal_depth (s : V → ℕ) (hs : G.ValidSchedule s) :
    G.depth ≤ Finset.univ.sup s := by
  classical
  exact Finset.sup_le (fun v _ => (G.level_minimal s hs v).trans
    (Finset.le_sup (Finset.mem_univ v)))
```

Proof reading. The earlier `level_minimal` theorem proves by well-founded induction that the constructed level is no later than any positive valid schedule at each vertex. Taking the finite maximum yields the displayed lower bound. Separate declarations prove the level schedule valid and its maximum attained by a path, so the construction is optimal in the unit-duration, unrestricted-parallelism model. Device resources, variable task durations, and launch overhead are outside that model.

6.5 Actual forward substitution in dependent block spaces

For each vertex v, `X v` is its block space. Unequal block dimensions are allowed. `D v : X v ≃ₗ[K] X v` is an invertible linear map, and `T b a` is a linear transfer from the source space to the target space. The action sums only graph edges.

Source: `formalization/TriangularSolve.lean`.

Exact lines 38–43. Excerpt `solve_correct`. SHA-256 in Section 15.

```
theorem solve_correct (rhs : ∀ v, X v) :
    G.triangularAction X D T (G.solve X D T rhs) = rhs := by
  funext v
  unfold triangularAction
  rw [G.solve_eq X D T rhs v, LinearEquiv.apply_symm_apply]
  exact sub_add_cancel _ _
```

Proof reading. The constructed `solve` uses well-founded forward substitution, applying `(D v).symm` to the right-hand side minus previously solved transfers. Function extensionality chooses one vertex. Rewrite the solve equation, cancel the inverse linear equivalence, then add back the transfer sum. Uniqueness is a separate well-founded induction over the same graph. The staged solver is separately proved correct through each level. The theorem begins with no assumed solution or solve equation.

7 Error propagation and exact precision allocation

7.1 Local block errors are actual operators

Contract. `PacketPerturbation` works over a nontrivially normed field and a normed vector space. `A e` and `Δ e` are continuous linear maps. The source-support hypothesis is `Δ e = (Δ e).comp (P (src e))`.

Source: `formalization/PacketPerturbation.lean`.

Exact lines 35–39. Excerpt `packet_error`. SHA-256 in Section 15.

```
theorem packet_perturbation_bound (P : I → X →L[K] X) (src : E → I)
    (A Δ : E → X →L[K] X) (hΔ : ∀ e, Δ e = (Δ e).comp (P (src e))) (x : X) :
    ‖((∑ e, (A e + Δ e)) - (∑ e, A e)) x‖ ≤ ∑ e, ‖Δ e‖ * ‖P (src e) x‖ := by
  rw [packet_error_action_identity P src A Δ hΔ]
  exact (norm_sum_le _ _).trans (Finset.sum_le_sum (fun e _ => (Δ e).le_opNorm _))
```

Proof reading. Rewrite the total action error as a sum of source-supported error actions. The triangle inequality bounds the norm of that sum. Each map's operator-norm estimate supplies $\|\Delta_e\|\|P_{\mathrm{src}(e)}x\|$. The exact support of the A_e terms is not required for this inequality. A later theorem assumes local relative budgets. Another adds contractive source projectors for a uniform certificate. Neither conclusion certifies IEEE arithmetic or a specific CUDA kernel.

7.2 Products preserve multiplication order

Contract. `ProductChainError` uses a normed ring. The product-chain endpoint additionally assumes `NormOneClass R`, so the empty product has norm one. Products are built by left multiplication at each successor step.

Source: `formalization/ProductChainError.lean`.

Exact lines 129–145. Excerpt `chain_error`. SHA-256 in Section 15.

```
theorem product_chain_error_bound [NormOneClass R] (A B : ℕ → R) (δ : ℕ → ℝ)
    (hδ : ∀ j, ‖B j - A j‖ ≤ δ j) (n : ℕ) :
    ‖chainProduct B n - chainProduct A n‖ ≤
      ∑ j ∈ Finset.range n,
        (∏ i ∈ Finset.Ico (j + 1) n, ‖B i‖) *
          (δ j * ∏ i ∈ Finset.range j, ‖A i‖) := by
  rw [← propagatedError_eq_sum]
  apply norm_recurrence_bound (fun k => chainProduct B k - chainProduct A k)
    (fun k => ‖B k‖) (fun k => δ k * ∏ i ∈ Finset.range k, ‖A i‖)
    (by simp [chainProduct]) (fun k => norm_nonneg _)
  intro k
  rw [product_discrepancy_step]
  apply (norm_add_le _ _).trans
  apply add_le_add (norm_mul_le _ _)
  apply (norm_mul_le _ _).trans
  exact mul_le_mul (hδ k) (chainProduct_norm_bound A k) (norm_nonneg _)
    ((norm_nonneg _).trans (hδ k))
```

Proof reading. The discrepancy at a successor splits into the perturbed factor times the previous discrepancy, plus the new local error times the exact prefix. The generic norm recurrence propagates these two contributions. Its unrolled finite sum uses perturbed suffix norms and exact prefix norms in the displayed order. Submultiplicativity and the local error bound close each successor estimate. The empty chain has zero discrepancy. No commutativity is used.

Source: `formalization/ProductChainError.lean`.

Exact lines 100–111. Excerpt `recompression_error`. SHA-256 in Section 15.

```
theorem repeated_recompression_bound (A E : ℕ → R) (δ : ℕ → ℝ)
    (hδ : ∀ j, ‖E j‖ ≤ δ j) (n : ℕ) :
    ‖recompressedProduct A E n - chainProduct A n‖ ≤
      ∑ j ∈ Finset.range n, (∏ i ∈ Finset.Ico (j + 1) n, ‖A i‖) * δ j := by
  rw [← propagatedError_eq_sum]
  apply norm_recurrence_bound
      (fun k => recompressedProduct A E k - chainProduct A k)
      (fun k => ‖A k‖) δ (by simp [chainProduct, recompressedProduct])
      (fun k => norm_nonneg _)
  intro k
  rw [recompression_discrepancy_step]
  exact (norm_add_le _ _).trans (add_le_add (norm_mul_le _ _) (hδ k))
```

Proof reading. Here each iterate has an additive residual `E j` after multiplication by `A j`. The successor error is A_j times the old error plus E_j. The same recurrence yields the product of subsequent operator norms times each certified residual budget. This theorem uses actual residuals with verified bounds. It does not itself choose the recompression algorithm or infer its floating-point error.

7.3 The continuous minimizer is global

The finite edge type is explicitly nonempty. Every sensitivity s_e, cost c_e, and budget is positive. `AllocationFeasible` requires positive tolerances and exact weighted budget equality. The objective is $\sum_e c_e \log(1/\varepsilon_e)$, and the candidate is

$$\varepsilon_e^* = \frac{\mathrm{budget}\, c_e}{s_e \sum_f c_f}.$$

Source: `formalization/ContinuousPrecision.lean`.

Exact lines 80–97. Excerpt `continuous_precision`. SHA-256 in Section 15.

```
theorem precision_allocation_optimal [Nonempty E] (s c : E → ℝ) (budget : ℝ)
    (hs : ∀ e, 0 < s e) (hc : ∀ e, 0 < c e) (hb : 0 < budget)
    (eps : E → ℝ) (heps : AllocationFeasible s budget eps) :
    precisionObjective c (optimalTolerance s c budget) ≤ precisionObjective c eps := by
  have ho := optimal_tolerance_positive s c budget hs hc hb
  have hbalance := relative_budget_identity s c eps budget hs hc hb heps.2
  have hlog : (∑ e, c e * Real.log (eps e / optimalTolerance s c budget e)) ≤ 0 := by
    calc
      _ ≤ ∑ e, c e * (eps e / optimalTolerance s c budget e - 1) := by
        apply Finset.sum_le_sum
        intro e _
```

```
        exact mul_le_mul_of_nonneg_left
          (Real.log_le_sub_one_of_pos (div_pos (heps.1 e) (ho e))) (le_of_lt (hc e))
      _ = 0 := by
        simp_rw [mul_sub, mul_one]
        rw [Finset.sum_sub_distrib, hbalance, sub_self]
  have hd := precision_objective_difference c eps (optimalTolerance s c budget) heps.1 ho
  linarith
```

Proof reading. First prove positivity of the candidate and an exact weighted-ratio balance. Compare each competitor ratio $\varepsilon_e/\varepsilon_e^*$ with the inequality $\log x \le x - 1$. Multiply by nonnegative costs and sum. The balance makes the upper sum zero, and the objective-difference identity changes its sign to obtain the global lower bound. The strict logarithmic inequality at a differing edge gives strictness and then uniqueness in subsequent declarations. The proof uses no stationary-point optimality assumption.

7.4 Caps separate the allocation from its multiplier

`clippedTolerance s c m t e` is $\min(m_e, tc_e/s_e)$. The cap vector is positive. The budget is positive and no larger than the total weighted cap. A continuous monotone total-allocation function yields an attaining positive scale.

Source: `formalization/ClippedPrecision.lean`.

Exact lines 211–234. Excerpt `clipped_precision`. SHA-256 in Section 15.

```
theorem clipped_unique_minimizer [Nonempty E] (s c m : E → ℝ) (budget : ℝ)
    (hs : ∀ e, 0 < s e) (hc : ∀ e, 0 < c e) (hm : ∀ e, 0 < m e)
    (hb : 0 < budget) (hcap : budget ≤ ∑ e, s e * m e) :
    ∃ t, 0 < t ∧ ClippedFeasible s m budget (clippedTolerance s c m t) ∧
      ∀ eps, ClippedFeasible s m budget eps →
        ((∀ other, ClippedFeasible s m budget other →
            precisionObjective c eps ≤ precisionObjective c other) ↔
          eps = clippedTolerance s c m t) := by
  obtain ⟨t, ht, heq⟩ := clipped_scale_exists s c m budget hs hc hm hb hcap
  have hf : ClippedFeasible s m budget (clippedTolerance s c m t) :=
    ⟨⟨clipped_positive s c m t hs hc hm ht, heq⟩, fun _ => min_le_left _ _⟩
  refine ⟨t, ht, hf, ?_⟩
  intro eps heps
  constructor
  · intro hmin
    by_contra hne
    have hl := clipped_allocation_strict s c m budget t hs hc hm ht heq eps heps hne
    have hu := hmin _ hf
    linarith
  · intro h
    subst eps
    exact fun other hother => clipped_allocation_optimal s c m budget t hs hc hm ht heq other
      ↪ hother

/- The parameter is the reciprocal of the manuscript's multiplier. -/
```

Proof reading. Obtain an attaining scale from `clipped_scale_exists`. Its positivity and budget identity establish feasibility. The minimum supplies the cap inequalities. A distinct feasible vector

has strictly larger objective by the supporting logarithmic inequality. This rules out every competing minimizer and gives the equivalence with the constructed tolerance vector. At total-cap budget, the tolerance vector remains unique but the scale, and hence the reciprocal multiplier, need not be unique. The endpoint-nonuniqueness declaration records that distinction.

7.5 Discrete choices guard natural subtraction

Each edge has a finite list of pairs: quantized error weight in $\mathbb{N}$ and exact ordered-field cost. `Assignment edges` independently chooses one listed option per edge. An empty option list is infeasible, while an empty edge list has the empty assignment.

Source: `formalization/DiscretePrecision.lean`.

Exact lines 38–42. Excerpt `discrete_recurrence`. SHA-256 in Section 15.

```
def discreteTable : List (List (ℕ × R)) → ℕ → Option R
  | [], b => singletonTable 0 0 b
  | opts :: edges, b =>
    bestOver (fun o => if o.1 ≤ b then
      add (discreteTable edges (b - o.1)) (some o.2) else none) opts
```

Proof reading. The recursive table records exact total weight. Its guard checks that the current option fits before using `b - o.1`. Natural subtraction truncates at zero, so an unguarded recurrence could accept an overweight option through a zero residual. The development proves exact-weight semantics by induction on the edge list, then scans weights up to the budget. Zero-error options are allowed.

Source: `formalization/DiscretePrecision.lean`.

Exact lines 110–121. Excerpt `discrete_endpoint`. SHA-256 in Section 15.

```
theorem discreteBudget_some_iff (edges : List (List (ℕ × R))) (B : ℕ) (v : R) :
    discreteBudget edges B = some v ↔
      (∃ a : Assignment edges, a.weight ≤ B ∧ a.cost = v) ∧
        ∀ a : Assignment edges, a.weight ≤ B → v ≤ a.cost := by
  rw [minimum_some_iff _ _ (discrete_precision_program edges B)]
  constructor
  · intro h
    exact ⟨h.1, fun a ha => h.2 _ ⟨a, ha, rfl⟩⟩
  · intro h
    refine ⟨h.1, ?_⟩
    rintro z ⟨a, ha, rfl⟩
    exact h.2 a ha
```

Proof reading. The returned `some v` is equivalent to an attained feasible assignment cost together with a lower bound for every feasible assignment. The helper's `IsMinimum` semantics guarantees both parts. The proof translates its value predicate back to an actual assignment. The companion `discreteBudget_none_iff` equates `none` with absence of a complete feasible assignment. Finite sentinel costs are never substituted for infeasibility.

8 Exact packet compilation and cached refinement

8.1 An independently defined feasible set

The tree label type α contains application-specific packet choices. Internal nodes have `arity + 1` children, so this constructor has at least one child. Costs live in a linearly ordered field with its compatible strict ring order. This permits exact rational execution as well as real-valued models.

Source: `formalization/ExactTreeCompiler.lean`.

Exact lines 21–23. Excerpt `candidate_tree`. SHA-256 in Section 15.

```
inductive CandidateTree (α : Type*) where
  | leaf (label : α)
  | node (label : α) (arity : ℕ) (children : Fin (arity + 1) → CandidateTree α)
```

Source: `formalization/ExactTreeCompiler.lean`.

Exact lines 33–36. Excerpt `cut`. SHA-256 in Section 15.

```
inductive Cut : CandidateTree α → Type _ where
  | keep (t : CandidateTree α) : Cut t
  | split {a : α} {n : ℕ} {ts : Fin (n + 1) → CandidateTree α}
      (cs : ∀ i, Cut (ts i)) : Cut (.node a n ts)
```

Proof reading. `Cut t` is indexed by the tree it prunes. Keeping a tree gives a legal cut, while splitting an internal node requires one legal cut of every child. This type is defined before the optimization recurrence. Therefore correctness has an independent feasible set against which to compare the recurrence.

Source: `formalization/ExactTreeCompiler.lean`.

Exact lines 45–47. Excerpt `tree_recurrence`. SHA-256 in Section 15.

```
def optimalValue (keep overhead : α → R) : CandidateTree α → R
  | .leaf a => keep a
  | .node a _ ts => min (keep a) (overhead a + ∑ i, optimalValue keep overhead (ts i))
```

Proof reading. A leaf must be kept. At an internal node, compare the node's keep cost against the split overhead plus child optimal values. The proof `optimalValue_le_cut` proceeds by induction on the tree and cases on a legal cut. Keeping selects the left minimum bound, while splitting combines the right minimum bound with all child bounds.

Source: `formalization/ExactTreeCompiler.lean`.

Exact lines 69–76. Excerpt `compile_attains`. SHA-256 in Section 15.

```
theorem compile_attains (keep overhead : α → R) (t : CandidateTree α) :
    cutValue keep overhead (compile keep overhead t) = optimalValue keep overhead t := by
  induction t with
  | leaf a => rfl
  | node a n ts ih =>
    by_cases h : keep a ≤ overhead a + ∑ i, optimalValue keep overhead (ts i)
    · simp [compile, h, cutValue, root, optimalValue]
    · simp [compile, h, cutValue, ih, optimalValue, min_eq_right (le_of_not_ge h)]
```

Proof reading. The actual `compile` returns a cut and chooses keep at ties. Induction proves its objective equals the recurrence. If the keep comparison holds, simplifying the conditional proves the keep case. Otherwise the induction hypotheses rewrite every compiled child cost and the right branch realizes the minimum.

Source: `formalization/ExactTreeCompiler.lean`.

Exact lines 79–83. Excerpt `tree_exact`. SHA-256 in Section 15.

```
theorem exact_tree_compiler (keep overhead : α → R) (t : CandidateTree α) :
    (∀ c : Cut t, optimalValue keep overhead t ≤ cutValue keep overhead c) ∧
    ∃ c : Cut t, cutValue keep overhead c = optimalValue keep overhead t := by
  exact ⟨optimalValue_le_cut keep overhead t, compile keep overhead t,
    compile_attains keep overhead t⟩
```

Proof reading. The final conjunction pairs the universal lower bound with the constructed attaining cut. Optimality is thus stronger than a recurrence-value identity. Lagrangian compilation later specializes keep scores to cost plus multiplier times error. Weighted families combine their actual cut objectives before applying this same theorem.

8.2 The Pareto statement has a boundary

The monotone-frontier theorem compares two genuinely optimal cuts at distinct nonnegative multipliers. Adding the two optimality inequalities bounds their errors in opposite order to their costs. A positive-multiplier optimum is Pareto efficient. The source also includes `unsupported_pareto_example`: weighted sums need not select every efficient point of a discrete feasible set. The exact budget compiler therefore has a separate role.

8.3 An exact quantized table

Source: `formalization/QuantizedTreeCompiler.lean`.

Exact lines 27–33. Excerpt `budget_recurrence`. SHA-256 in Section 15.

```
def budgetTable (κ : α → R) (w : α → ℕ) (σ : α → R) :
    CandidateTree α → ℕ → Option R
  | .leaf a, b => BudgetDP.singletonTable (w a) (κ a) b
  | .node a _ ts, b =>
    BudgetDP.choose (BudgetDP.singletonTable (w a) (κ a) b)
      (BudgetDP.add (some (σ a))
        (BudgetDP.combine (fun i => budgetTable κ w σ (ts i)) b))
```

Proof reading. Each keep option occupies its exact weight, while splitting convolves the child exact-weight tables and adds overhead. `BudgetDP.choose` compares two attainable options. The min-plus infrastructure proves that sums and finite choices preserve the independent `IsMinimum` predicate. Induction on the actual candidate tree therefore connects every table entry to legal cuts of exactly that weight.

Source: formalization/QuantizedTreeCompiler.lean.

Exact lines 107–119. Excerpt budget_endpoint. SHA-256 in Section 15.

```
theorem compileBudget_some_iff (κ : α → R) (w : α → ℕ) (σ : α → R)
    (t : CandidateTree α) (B : ℕ) (v : R) :
    compileBudget κ w σ t B = some v ↔
      (∃ c : Cut t, cutWeight w c ≤ B ∧ cutValue κ σ c = v) ∧
      ∀ c : Cut t, cutWeight w c ≤ B → v ≤ cutValue κ σ c := by
  rw [BudgetDP.minimum_some_iff _ _ (quantized_budget_compiler κ w σ t B)]
  constructor
  · intro h
    exact ⟨h.1, fun c hc => h.2 _ ⟨c, hc, rfl⟩⟩
  · intro h
    refine ⟨h.1, ?_⟩
    rintro z ⟨c, hc, rfl⟩
    exact h.2 c hc
```

Proof reading. The budget scan ranges over weights from zero through B. The endpoint states that a finite answer is attained by a legal cut of weight at most B, and no feasible cut costs less. This is an optimum over the original tree's cuts, rather than a continuous relaxation or a weighted-sum surrogate.

Source: formalization/QuantizedTreeCompiler.lean.

Exact lines 122–126. Excerpt budget_none. SHA-256 in Section 15.

```
theorem compileBudget_none_iff (κ : α → R) (w : α → ℕ) (σ : α → R)
    (t : CandidateTree α) (B : ℕ) :
    compileBudget κ w σ t B = none ↔ ¬ ∃ c : Cut t, cutWeight w c ≤ B := by
  rw [BudgetDP.minimum_none_iff _ _ (quantized_budget_compiler κ w σ t B)]
  simp
```

Proof reading. The infeasibility branch is exactly the negation of the existence of a budget-feasible legal cut. Both directions follow from the same proved minimum semantics. This is why the option-valued model distinguishes none from an expensive but attainable value.

8.4 The specification and stored implementation are separate

The functional recurrence above is a convenient specification. Evaluating it independently at many weights can recompute child tables. StoredBudgetCompiler adds vectors of $B+1$ option-valued entries, bounded lookup, tabulation, cached child arrays, and stored min-plus merges.

Source: formalization/StoredBudgetCompiler.lean.

Exact lines 109–118. Excerpt stored_tree. SHA-256 in Section 15.

```
def storedTree (B : ℕ) (κ : α → R) (w : α → ℕ) (σ : α → R) :
    CandidateTree α → BudgetDP.StoredTable R B
  | .leaf a => BudgetDP.tabulate B (BudgetDP.singletonTable (w a) (κ a))
  | .node a n ts =>
    let cached := Vector.ofFn (fun i => storedTree B κ w σ (ts i))
    let merged := BudgetDP.combineStored (fun i : Fin (n + 1) => cached.get i)
```

```
    BudgetDP.tabulate B (fun b => BudgetDP.choose (BudgetDP.singletonTable (w a) (κ a) b)
      (BudgetDP.add (some (σ a)) (BudgetDP.lookup merged b)))

/- The implemented cached array agrees entrywise with the proved exact recurrence. -/
```

Proof reading. At a node, `Vector.ofFn` computes the child arrays before combining them. The final tabulation reads the merged array at each requested weight. Every array is finite and each child result is reused. The loop structure justifies the stored-table work model. It is not inferred from the earlier functional recurrence.

Source: `formalization/StoredBudgetCompiler.lean`.

Exact lines 120–133. Excerpt `stored_correct`. SHA-256 in Section 15.

```
theorem storedTree_correct (B : ℕ) (κ : α → R) (w : α → ℕ) (σ : α → R)
    (t : CandidateTree α) (b : ℕ) (hb : b ≤ B) :
    BudgetDP.lookup (storedTree B κ w σ t) b = budgetTable κ w σ t b := by
  induction t generalizing b with
  | leaf a => exact BudgetDP.lookup_tabulate B _ b hb
  | node a n ts ih =>
    simp only [storedTree, budgetTable, BudgetDP.lookup_tabulate _ _ _ hb]
    congr 2
    rw [BudgetDP.combineStored_correct _ b hb]
    apply BudgetDP.combine_congr_local
    intro i k hk
    simpa only [BudgetDP.vector_get_ofFn] using ih i k (hk.trans hb)

/- The executable tabulated compiler scans its stored root table. -/
```

Proof reading. Induct on the tree. The leaf is bounded lookup of a tabulated singleton. At a node, unfold the two constructions, use correctness of stored child combination, and restrict convolution dependencies to indices no larger than the queried weight. Apply each child induction hypothesis within that bound. This yields entrywise equality with the specification. The stored optimizer's attained minimum is then derived from the already proved specification semantics.

Source: `formalization/StoredBudgetCompiler.lean`.

Exact lines 256–260. Excerpt `pseudo_polynomial`. SHA-256 in Section 15.

```
theorem tabulation_pseudopolynomial (B : ℕ) (t : CandidateTree α) :
    tabulationWork B t ≤ nodeCount t * (3 * (B + 1) + (B + 1)^2) := by
  have h := tabulation_work_bound B t
  have hm := mergeCount_add_one t
  nlinarith
```

Proof reading. The source separately defines the tabulation work and number of merges. The bound `tabulation_work_bound` supplies per-node table and merge costs, and `mergeCount_add_one` relates merges to the tree size. Algebra combines them into the displayed bound. The complexity is polynomial in the numeric budget B, so pseudo-polynomial in a binary encoding. Costs are unit-cost table cells and candidate trials. Arbitrary-precision bit complexity, compiler runtime, and device timing are excluded.

8.5 Stability requires controlled branch gaps

Source: `formalization/TreeCompilerUpdates.lean`.

Exact lines 45–59. Excerpt `compiler_stability`. SHA-256 in Section 15.

```
theorem compiler_stability (keep overhead keep' overhead' : α → R)
    (t : CandidateTree α) (hg : GapControlled keep overhead keep' overhead' t) :
    compile keep' overhead' t = compile keep overhead t := by
  induction t with
  | leaf a => rfl
  | node a n ts ih =>
    rcases hg with ⟨hk, hs, hc⟩
    have ho := half_gap_order _ _ _ _ hk hs
    simp only [compile]
    by_cases h : keep a ≤ overhead a + ∑ i, optimalValue keep overhead (ts i)
    · rw [ite_eq_left h, ite_eq_left (ho.mpr h)]
    · rw [ite_eq_right h, ite_eq_right (fun hp => h (ho.mp hp))]
      congr 1
      funext i
      exact ih i (hc i)
```

Proof reading. `GapControlled` recursively supplies bounds on perturbations of keep and split scores, including all child problems. `half_gap_order` proves the original and perturbed comparisons have the same truth value. The proof follows the two branches of `compile`. When both split, induction identifies every child cut. A near tie without this control is not covered by an unchanged-decision guarantee.

Source: `formalization/TreeCompilerUpdates.lean`.

Exact lines 142–150. Excerpt `local_update`. SHA-256 in Section 15.

```
theorem local_recompilation (keep overhead : α → R) (ctx : CachedContext α R)
    (hv : Valid keep overhead ctx) (newTree : CandidateTree α) :
    (∀ c : Cut (fill ctx newTree),
      updateValue keep overhead ctx (optimalValue keep overhead newTree) ≤
        cutValue keep overhead c) ∧
    ∃ c : Cut (fill ctx newTree), cutValue keep overhead c =
      updateValue keep overhead ctx (optimalValue keep overhead newTree) := by
  rw [updateValue_correct keep overhead ctx hv newTree]
  exact exact_tree_compiler keep overhead (fill ctx newTree)
```

Proof reading. A `CachedContext` stores the ancestor context around a replaced subtree, including sibling data. `Valid` asserts those cached values match their subtree optima. `updateValue_correct` identifies the refreshed root value with the optimum of the filled tree. The exact compiler theorem then supplies its lower bound and attaining witness. Separate declarations prove sibling trees and sibling values unchanged. The displayed theorem is correctness of local recomputation. A hardware time-saving claim requires its own execution evidence.

9 Output contracts, batching, and Krylov certificates

9.1 The decoding map is part of the contract

The signature for a fair timing comparison contains a case key, output contract, reference, and timing scope. Equality of those four fields defines `FairMatch`. The source proves that it is an equivalence relation. This theorem does not establish that recorded benchmark metadata contain every field needed to instantiate the relation.

Source: `formalization/SchedulingContracts.lean`.

Exact lines 54–60. Excerpt `contract`. SHA-256 in Section 15.

```
theorem contract_conversion {X C Y : Type*} (compressed : X → C) (explicit : X → Y)
    (decode : C → Y) (runTime : X → ℝ) (decodeTime : C → ℝ)
    (hdecode : ∀ x, decode (compressed x) = explicit x) (x : X) :
    (decodedRun compressed decode runTime decodeTime x).1 = explicit x ∧
    (decodedRun compressed decode runTime decodeTime x).2 =
      runTime x + decodeTime (compressed x) := by
  exact ⟨hdecode x, rfl⟩
```

Proof reading. The hypothesis `hdecode` says the actual decoding function converts the compressed result to the requested explicit object. The modeled decoded run returns that object and adds the declared conversion time. The two conclusion components follow from the decoding identity and the definition. The times are input models, so the theorem does not independently verify their measurement. A separate declaration shows that omitting a positive decoding time understates the modeled total.

9.2 Grouping preserves all contributions

Source: `formalization/SchedulingContracts.lean`.

Exact lines 89–93. Excerpt `grouping`. SHA-256 in Section 15.

```
theorem grouped_execution_output {E Shape V : Type*} [Fintype E] [DecidableEq Shape]
    [AddCommMonoid V] (key : E → Shape) (value : E → V) :
    (∑ k ∈ activeShapeClasses key, ∑ e ∈ Finset.univ.filter (fun e => key e = k), value e) =
      ∑ e, value e := by
  exact Finset.sum_fiberwise_of_maps_to (fun e _ => each_block_has_shape key e) value
```

Proof reading. The complete kernel key maps every active event to one shape class. Summing over the image classes and their fibers reindexes the original finite sum, and the library's fiberwise sum theorem proves equality. The companion work theorem repeats this identity for natural-valued work. The launch-count theorem bounds the number of classes by the number of events. The model requires that the key really include the fields needed for a common kernel. It does not verify an arbitrary runtime grouping implementation.

9.3 Strict profitability uses floor plus one

Source: `formalization/SchedulingContracts.lean`.

Exact lines 117–123. Excerpt `amortization`. SHA-256 in Section 15.

```
theorem integer_amortization_threshold (setup baseline candidate : ℝ)
    (hs : 0 ≤ setup) (h : candidate < baseline) (reuse : ℕ) :
    setup + (reuse : ℝ) * candidate < (reuse : ℝ) * baseline ↔
      minimumReuse setup baseline candidate ≤ reuse := by
  rw [amortization_threshold setup baseline candidate reuse h, minimumReuse]
  rw [← Nat.floor_lt (div_nonneg hs (le_of_lt (sub_pos.mpr h)))]
  omega
```

Proof reading. With nonnegative setup and a strictly smaller per-use candidate time, solve the strict total-cost inequality by division through the positive saving. The natural floor lemma converts a strict real threshold into the minimum integer reuse. Equality at break-even is not a profitable use, which accounts for the added one. The minimum-attainment theorem checks that threshold and all smaller reuse counts. Capture/replay and materialization have separate specializations with their own premises.

9.4 Invariant packet Krylov spaces

Contract. The Krylov development uses bounded linear maps on a normed space over a nontrivially normed field, with a finite packet family. The exact theorem assumes the operator commutes with every packet projector.

Source: `formalization/KrylovPackets.lean`.

Exact lines 89–99. Excerpt `krylov`. SHA-256 in Section 15.

```
theorem invariant_packet_krylov (P : PacketFamily (X →L[K] X) I)
    (A : X →L[K] X) (hA : ∀ i, Commute A (P.proj i)) (v : X) (m : ℕ) :
    krylovSpace A v m ≤ ⨆ i, krylovSpace (P.block A i i) (P.proj i v) m := by
  apply Submodule.span_le.mpr
  rintro x ⟨j, rfl⟩
  change (A ^ j.val) v ∈ (⨆ i, krylovSpace (P.block A i i) (P.proj i v) m : Submodule K X)
  rw [invariant_packet_power_expansion P A hA v j.val]
  apply Submodule.sum_mem
  intro i _
  exact Submodule.mem_iSup_of_mem i
    (krylov_generator_mem (P.block A i i) (P.proj i v) m j.val j.isLt)
```

Proof reading. To prove inclusion of a span, it suffices to prove membership for each generator $A^j v$. The preceding exact power-expansion theorem writes that generator as the sum of local packet powers acting on projected seeds. Each term belongs to its local Krylov subspace, hence to the supremum of those spaces. The finite sum remains inside. This endpoint is an inclusion. `local_krylov_direct` separately proves directness using the mutually annihilating packet projectors. It does not assert equality of the global seed Krylov space with the full independent sum of all local spaces.

Source: formalization/KrylovPackets.lean.

Exact lines 183–195. Excerpt approx_krylov. SHA-256 in Section 15.

```
theorem approximate_packet_krylov_distance (P : PacketFamily (X →L[K] X) I)
    (D E : X →L[K] X) (hD : PacketDiagonal P D) (v : X) (j : ℕ) (hj : 0 < j) :
    Metric.infDist (((D + E) ^ j) v)
      ((⨆ i, krylovSpace (P.block D i i) (P.proj i v) (j + 1) : Submodule K X) : Set X) ≤
      (j : ℝ) * (max ‖D + E‖ ‖D‖) ^ (j - 1) * ‖E‖ * ‖v‖ := by
  have hm : (D ^ j) v ∈ (⨆ i, krylovSpace (P.block D i i) (P.proj i v) (j + 1) : Submodule K X)
   ↪  :=
    invariant_packet_krylov P D (packet_diagonal_commutes P D hD) v (j + 1)
      (krylov_generator_mem D v (j + 1) j (Nat.lt_succ_self j))
  calc
    _ ≤ dist (((D + E) ^ j) v) ((D ^ j) v) := Metric.infDist_le_dist_of_mem hm
    _ = ‖((D + E) ^ j - D ^ j) v‖ := by rw [dist_eq_norm]; rfl
    _ ≤ ‖(D + E) ^ j - D ^ j‖ * ‖v‖ := ((D + E) ^ j - D ^ j).le_opNorm v
    _ ≤ _ := mul_le_mul_of_nonneg_right (approximate_packet_power_bound D E j hj) (norm_nonneg _)
```

Proof reading. Packet diagonality of D gives commutation, so $D^j v$ lies in the local Krylov sum of length $j+1$. The distance to that subspace is no larger than the distance to this particular vector. Bound the difference action by its operator norm, then apply the power-perturbation estimate. The displayed premise 0 < j permits the exponent $j-1$. A zero-power identity is handled separately in the power development.

9.5 The Jacobi normalization uses the L2 operator norm

invSqrt D is the actual inverse of the positive matrix square root CFC.sqrt D. matrixCondition A is the product of the Euclidean operator norms of A and its inverse. The matrix index type is finite and nonempty at the condition-bound endpoint. Positivity and invertibility assumptions are explicit.

Source: formalization/BlockJacobi.lean.

Exact lines 87–95. Excerpt jacobi. SHA-256 in Section 15.

```
theorem block_jacobi_condition (D K : Matrix X X ℂ)
    (hD : D.PosDef) (hA : (D+K).PosDef) (η : ℝ)
    (hE : ‖invSqrt D*K*invSqrt D‖ ≤ η) (hη : η < 1) :
    matrixCondition (invSqrt D*(D+K)*invSqrt D) ≤ (1+η)/(1-η) := by
  have hunit := ((invSqrt_isUnit D hD).mul hA.isUnit).mul (invSqrt_isUnit D hD)
  have hdet := (Matrix.isUnit_iff_isUnit_det _).mp hunit
  have hinv := Matrix.mul_nonsing_inv (invSqrt D*(D+K)*invSqrt D) hdet
  rw [normalized_decomposition D K hD] at hinv ⊢
  exact near_one_condition_bound _ _ hinv η hE hη
```

Proof reading. Positive definiteness of D proves its inverse square root is a unit, and positive definiteness of $D+K$ proves the normalized matrix is a unit. Its inverse identity is therefore justified. The normalization theorem writes the matrix as $I+E$, and the near-one condition estimate uses $\|E\| \le \eta < 1$. The theorem requires that supplied norm bound. It does not compute an empirical estimator of η.

Source: formalization/BlockJacobi.lean.

Exact lines 134–141. Excerpt cg_bound. SHA-256 in Section 15.

```
theorem certified_energy_error {κ κmax e0 em : ℝ} (m : ℕ)
    (hκ : 1 ≤ κ) (hbound : κ ≤ κmax) (he0 : 0 ≤ e0)
    (hCG : em ≤ 2*(cgFactor κ)^m*e0) :
    em ≤ 2*(cgFactor κmax)^m*e0 := by
  have hp : (cgFactor κ)^m ≤ (cgFactor κmax)^m :=
    pow_le_pow_left₀ (cgFactor_nonneg hκ) (cgFactor_mono hbound) m
  exact hCG.trans (mul_le_mul_of_nonneg_right
    (mul_le_mul_of_nonneg_left hp (by norm_num)) he0)
```

Proof reading. The classical CG energy-error estimate is the hypothesis hCG. The proved monotonicity of its convergence factor replaces the actual condition number by a certified upper bound. Nonnegativity permits raising the factor and multiplying the initial error. This is a formal comparison of factors and bounds. It does not independently prove CG iteration correctness or the classical convergence theorem. Item 7.5 stays a separate classical input.

9.6 Discovery residuals are orthogonal in Frobenius geometry

Source: formalization/DiscoveryCertificate.lean.

Exact lines 126–137. Excerpt discovery. SHA-256 in Section 15.

```
theorem discovery_frobenius_certificate (hP : ∀ a, (P.proj a)ᴴ = P.proj a)
    (A : Matrix X X ℂ) :
    ‖A-diagonalCompression P A‖^2 =
      ∑ b, ∑ a, if b=a then 0 else ‖P.block A b a‖^2 := by
  rw [compression_residual P A,
    frobenius_sum_sq (offDiagonalTerm P A) (offDiagonal_trace_orthogonal P hP A)]
  simp only [Fintype.sum_prod_type,offDiagonalTerm]
  apply Finset.sum_congr rfl
  intro b _
  apply Finset.sum_congr rfl
  intro a _
  by_cases h : b=a <;> simp [h]
```

Proof reading. Self-adjoint packet projectors make distinct block terms trace-orthogonal. The source first expresses the compression residual as its off-diagonal block sum. The finite Pythagorean identity for those terms gives the squared Frobenius norm as the sum of squared block norms, with diagonal terms zeroed. An operator-norm certificate is then derived from the Frobenius bound. This is exact geometry of a supplied packet family. Simultaneous spectral decomposition is a separately tracked classical input rather than an algorithm proved here.

10 Small-core optimal recompression from constructed ranges

10.1 The shape of the proof

The sixth block completes item 5.6 with ten modules and 79 new theorem declarations. Start with arbitrary finite complex matrices L and R of equal column type, including rank-deficient and zero factors. Construct compact orthonormal bases of their actual column spaces. Express LR^* as an isometric lift of its small core. Supply an ordered thin SVD of that core by its exact equations. Prove diagonal low-rank lower bounds, then transfer them to every ambient rank-bounded competitor. Finally construct factors with exactly $\min(d, k)$ columns.

Every stage has its own declarations. A general transfer lemma may accept core optimality as a premise. The final theorem discharges that premise with independently proved diagonal lower bounds. The supplied SVD data contain no optimality conclusion or singular-tail formula.

10.2 Compact dimensions are the actual matrix ranks

`columnSpace A` is the range of the actual Euclidean linear map associated with A. `compactDim A` is its finite dimension. `columnBasis A` chooses an orthonormal basis of that subspace. `compactQ A` represents its inclusion into the ambient space, and `compactR A` represents the range-restricted map in that basis.

Source: `formalization/CompactRangeFactors.lean`.

Exact lines 51–57. Excerpt `compact_factor`. SHA-256 in Section 15.

```
theorem compact_factorization (A : Matrix m n ℂ) : compactQ A * compactR A = A := by
  unfold compactQ compactR
  rw [←LinearMap.toMatrix_comp]
  have he : (columnSpace A).subtype ∘ₗ (Matrix.toEuclideanLin A).rangeRestrict =
      Matrix.toEuclideanLin A := by ext x i; rfl
  rw [he,Matrix.toEuclideanLin_eq_toLin_orthonormal]
  exact LinearMap.toMatrix_toLin _ _ _
```

Proof reading. Convert the product of the two coordinate matrices to the matrix of a composition. The inclusion composed with the range restriction is the original linear map, by entrywise reflexivity. Converting that map back to the original matrix proves the reconstruction. Separate theorems prove `compactDim A = A.rank`, orthonormality of `compactQ`, and full row rank of `compactR`. These are derived facts about actual matrices. The construction uses classical choice of an orthonormal basis. It is not a numerical triangular QR procedure.

The actual factor core is compactR(L) compactR$(R)^*$. Its row and column dimensions equal the two original input ranks. Its rank equals the rank of LR^*. A numerical QR prototype can keep zero directions, so its reported intermediate size need not equal these compact dimensions. No numerical-to-formal correspondence is inferred from matching array shapes alone.

10.3 A best-rank conclusion quantifies over all competitors

Source: `formalization/SmallCoreTransfer.lean`.

Exact lines 16–17. Excerpt `best_rank`. SHA-256 in Section 15.

```
def BestRank (N : Matrix m n ℂ → ℝ) (A B : Matrix m n ℂ) (k : ℕ) : Prop :=
  B.rank ≤ k ∧ ∀ C, C.rank ≤ k → N (A-B) ≤ N (A-C)
```

Proof reading. `BestRank N A B k` combines a rank bound on the constructed approximation with the inequality for every matrix `C` of rank at most `k`. Its norm functional `N` is explicit. It neither restricts competitors to a chosen factorization nor assumes they live in the input column spaces.

For isometric rectangular factors Q, V, the source defines `lift` and `compress` by

$$\mathrm{lift}(Q, V, G) = QGV^*, \qquad \mathrm{compress}(Q, V, B) = Q^*BV.$$

The norm module proves that lifting preserves spectral and Frobenius norms, compression does not increase them, and compression does not increase rank. The spectral norm is the L2 operator norm, while the Frobenius norm is selected in its separate norm scope.

Source: `formalization/SmallCoreTransfer.lean`.

Exact lines 25–35. Excerpt `ambient_transfer`. SHA-256 in Section 15.

```
theorem spectral_best_lift (Q : Matrix m r ℂ) (V : Matrix n s ℂ)
    (hQ : Qᴴ*Q=1) (hV : Vᴴ*V=1) (G H : Matrix r s ℂ) (k : ℕ)
    (hbest : BestRank spectralNorm G H k) :
    BestRank spectralNorm (lift Q V G) (lift Q V H) k := by
  refine ⟨(rank_lift_le Q V H).trans hbest.1,fun B hB => ?_⟩
  calc
    spectralNorm (lift Q V G-lift Q V H) = spectralNorm (G-H) := by
      rw [←lift_sub,spectral_lift Q V hQ hV]
    _ ≤ spectralNorm (G-compress Q V B) := hbest.2 _ ((rank_compress_le Q V B).trans hB)
    _ = spectralNorm (compress Q V (lift Q V G-B)) := by rw [compressed_error Q V hQ hV]
    _ ≤ spectralNorm (lift Q V G-B) := spectral_compress_le Q V hQ hV _
```

Proof reading. Fix an arbitrary ambient competitor `B`. Its compressed matrix still has rank at most k. Compare the core approximation with this compressed competitor using the core best-rank hypothesis. Re-express that error as compression of the ambient error and use contraction. Isometric lifting preserves the approximation error exactly. The lifted approximation also has the required rank. This proves global ambient optimality, once the core premise is independently discharged. The parallel Frobenius lemma follows the same chain with its own norm facts.

10.4 The SVD input states equations, rather than desired conclusions

Source: `formalization/SmallCoreRecompression.lean`.

Exact lines 29–37. Excerpt `ordered_svd`. SHA-256 in Section 15.

```
structure OrderedThinSVD (G : Matrix r s ℂ) (d : ℕ) where
  left : Matrix r (Fin d) ℂ
  right : Matrix s (Fin d) ℂ
  values : Fin d → ℝ
  left_isometry : leftᴴ*left=1
  right_isometry : rightᴴ*right=1
  nonnegative : ∀ i, 0 ≤ values i
  sorted : Antitone values
  reconstruction : G=lift left right (diag values)
```

Proof reading. The two column matrices are isometries. Values are real, nonnegative, and antitone in the finite index order. Reconstruction says the core equals the isometric lift of their diagonal. These fields supply the exact algebraic thin SVD data. They assume no rank-bound optimality, tail error, norm preservation, or lower bound. They are also not a theorem that such data exist for every input or that a floating-point routine returns exact equations.

The formal dimension d is the number of supplied thin SVD columns. Zero values are permitted. The output column type `KeptColumn d k` retains indices below k. Its cardinality is proved to be $\min(d, k)$. Square roots are taken only of nonnegative retained values. No zero singular value is inverted.

10.5 The spectral lower bound has an actual kernel witness

For a competitor of rank at most $k < d$, restrict it to the first $k + 1$ coordinate directions. The restricted matrix has rank smaller than its domain dimension. Rank-nullity yields a nonzero kernel vector. The prefix embedding makes it an ambient vector supported in those coordinates.

Source: `formalization/SpectralOptimality.lean`.

Exact lines 55–82. Excerpt `kernel_witness`. SHA-256 in Section 15.

```
theorem prefix_kernel_witness (k : ℕ) (hk : k<d)
    (B : Matrix (Fin d) (Fin d) ℂ) (hB : B.rank≤k) :
    ∃ y : EuclideanSpace ℂ (Fin d), y≠0 ∧ B*ᵥ y=0 ∧
      ∀ i : Fin d, k+1 ≤ i.val → y i=0 := by
  let J := prefixEmbedding k (by omega : k+1≤d)
  have hj : Jᴴ*J=1 := prefix_isometry k _
  have hr : (B*J).rank < Fintype.card (Fin (k+1)) := by
    have := Matrix.rank_mul_le_left B J
    simp only [Fintype.card_fin]
    omega
  obtain ⟨z,hz,hbz⟩ := rank_lt_kernel_witness (B*J) hr
  let y : EuclideanSpace ℂ (Fin d) := WithLp.toLp 2 (J*ᵥ z)
  have hy : y≠0 := by
    intro he
    have he' : J*ᵥ z=0 := congrArg WithLp.ofLp he
    have hz' : (z : Fin (k+1) → ℂ)=0 := by
```

```
      calc
        (z : Fin (k+1) → ℂ) = (J^H*J)*ᵥ z := by rw [hj,Matrix.one_mulVec]
        _ = J^H*ᵥ(J*ᵥ z) := (Matrix.mulVec_mulVec _ _ _).symm
        _ = 0 := by rw [he',Matrix.mulVec_zero]
    apply hz
    exact (EuclideanSpace.equiv (Fin (k+1)) ℂ).injective hz'
  refine ⟨y,hy,?_,?_⟩
  · change B*ᵥ(J*ᵥ z)=0
    rw [Matrix.mulVec_mulVec]
    exact hbz
  · intro i hi
    exact prefix_support k _ z i hi
```

Proof reading. `rank_lt_kernel_witness` constructs a nonzero vector in the restricted kernel. The prefix embedding's isometry proves its image remains nonzero. Associativity of matrix-vector multiplication proves the competitor kills that image. The prefix-support lemma proves all later coordinates vanish. Thus the lower-bound argument has a concrete witness. It does not posit the existence of a favorable test vector as an independent assumption.

The diagonal action on that vector has norm at least the first discarded value times its vector norm. The competitor contributes zero, so the operator-norm inequality and positivity of the witness norm give the lower bound. If $k \geq d$, the first discarded value is defined to be zero and norm nonnegativity suffices.

Source: `formalization/SpectralOptimality.lean`.

Exact lines 120–125. Excerpt `spectral_best`. SHA-256 in Section 15.

```
theorem diagonal_spectral_best (σ : Fin d → ℝ) (hσ : ∀ i, 0≤σ i)
    (hsort : Antitone σ) (k : ℕ) :
    BestRank spectralNorm (diag σ) (diag (kept σ k)) k := by
  refine ⟨rank_kept_le σ k,fun B hB => ?_⟩
  rw [diagonal_residual,spectral_diagonal_tail σ hσ hsort]
  exact diagonal_spectral_lower σ hσ hsort k B hB
```

Proof reading. The retained diagonal has rank at most k. Its residual norm is the proved first-discarded-value formula. The separate `diagonal_spectral_lower` applies to every competitor and supplies the final comparison. Both the attained error and the universal lower bound are proved within the diagonal development.

10.6 The Frobenius lower bound uses kernel mass

Choose an orthonormal basis Q of the competitor's actual kernel. The row weights w_i of that basis are nonnegative, at most one, and sum to its dimension. Rank-nullity makes that total at least $d - k$. Decreasing squared singular values therefore allocate their least weighted mass at the tail.

Source: `formalization/FrobeniusOptimality.lean`.

Exact lines 35–60. Excerpt `weighted_tail`. SHA-256 in Section 15.

```
theorem weighted_tail_lower (a w : Fin d → ℝ) (ha : ∀ i, 0 ≤ a i)
    (hsort : Antitone a) (hw0 : ∀ i, 0 ≤ w i) (hw1 : ∀ i, w i ≤ 1)
```

```
    (k : ℕ) (hw : (d-k : ℕ) ≤ ∑ i,w i) :
    (∑ i, if i.val<k then (0:ℝ) else a i) ≤ ∑ i, a i*w i := by
  by_cases hk : k<d
  · let μ := a ⟨k,hk⟩
    have hμ : 0 ≤ μ := ha _
    have hp : ∀ i : Fin d,
        (if i.val<k then 0 else a i) + μ*(w i-(if i.val<k then 0 else 1)) ≤ a i*w i := by
      intro i
      by_cases hi : i.val<k
      · have hle : μ ≤ a i := hsort (by show i.val ≤ k; omega)
        simp only [hi,ite_true,zero_add,sub_zero]
        exact mul_le_mul_of_nonneg_right hle (hw0 i)
      · have hle : a i ≤ μ := hsort (by show k ≤ i.val; omega)
        simp only [hi,ite_false]
        nlinarith [mul_nonneg (sub_nonneg.mpr hle) (sub_nonneg.mpr (hw1 i))]
    have hs := Finset.sum_le_sum (fun i (_ : i ∈ (Finset.univ : Finset (Fin d))) => hp i)
    simp only [Finset.sum_add_distrib] at hs
    have ht := tail_indicator_sum (d:=d) k hk.le
    have hz : 0 ≤ μ*((∑ i,w i)-(d-k : ℕ)) := mul_nonneg hμ (sub_nonneg.mpr hw)
    rw [←Finset.mul_sum,Finset.sum_sub_distrib,ht] at hs
    linarith
  · have he : ∀ i : Fin d, i.val<k := fun i => by omega
    simp only [he,ite_true,Finset.sum_const_zero]
    exact Finset.sum_nonneg (fun i _ => mul_nonneg (ha i) (hw0 i))
```

Proof reading. For $k < d$, use the threshold value a_k. In the prefix, ordering bounds a_k above by a_i and nonnegative weights preserve the inequality. In the tail, $w_i \leq 1$ supplies the corresponding bound. Summing adds a nonnegative threshold times the excess total mass. The tail indicator sum is exactly $d - k$. For $k \geq d$, the tail sum is zero. This finite inequality is proved directly and invokes no Eckart–Young optimality theorem.

Source: `formalization/FrobeniusOptimality.lean`.

Exact lines 76–104. Excerpt `frobenius_lower`. SHA-256 in Section 15.

```
theorem diagonal_frobenius_lower (σ : Fin d → ℝ) (hσ : ∀ i, 0 ≤ σ i)
    (hsort : Antitone σ) (k : ℕ) (B : Matrix (Fin d) (Fin d) ℂ) (hB : B.rank≤k) :
    tailEnergy σ k ≤ frobeniusNorm (diag σ-B)^2 := by

  have hsort2 : Antitone (fun i => σ i^2) := by
    intro i j hij
    have hle := hsort hij
    nlinarith [hσ i,hσ j]
  have hl := weighted_tail_lower (fun i => σ i^2) (rowWeight Q)
    (fun i => sq_nonneg _) hsort2 (rowWeight_nonneg Q) (rowWeight_le_one Q hQ) k hw
```

```
  have he : tailEnergy σ k = ∑ i, if i.val<k then (0:ℝ) else σ i^2 := by
    unfold tailEnergy discarded
    apply Finset.sum_congr rfl
    intro i _
    split_ifs <;> simp
  rw [←he,←diagonal_frame_energy σ Q] at hl
  have hc := frobenius_right_compress_le Q hQ (diag σ-B)
  have hbq : (diag σ-B)*Q=diag σ*Q := by
    rw [Matrix.sub_mul,mul_kernelFrame,sub_zero]
  rw [hbq] at hc
  unfold frobeniusNorm at hl ⊢
  nlinarith [norm_nonneg (diag σ*Q),norm_nonneg (diag σ-B)]
```

Proof reading. Construct the actual kernel frame and establish its row-weight mass from rank-nullity. Apply the finite weighted-tail inequality to σ_i^2. The frame-energy identity converts its right side into the squared Frobenius norm of the diagonal action on the kernel frame. The competitor kills the frame, so the same action is the residual times that frame. Frobenius compression contraction bounds it by the full residual. Norm nonnegativity permits the final squared comparison.

10.7 Combining both optimalities and the exact errors

Source: `formalization/SmallCoreRecompression.lean`.

Exact lines 91–120. Excerpt `recompression_optimal`. SHA-256 in Section 15.

```
theorem recompression_optimality (Q : Matrix m r ℂ) (V : Matrix n s ℂ)
    (hQ : Qᴴ*Q=1) (hV : Vᴴ*V=1) {G : Matrix r s ℂ}
    (svd : OrderedThinSVD G d) (k : ℕ) :
    let A := lift Q V G
    let B := recompressLeft Q svd k * (recompressRight V svd k)ᴴ
    BestRank spectralNorm A B k ∧ BestRank frobeniusNorm A B k ∧

```

```
    have hn : 0 ≤ frobeniusNorm (diag (discarded svd.values k)) := by
      unfold frobeniusNorm
      exact norm_nonneg (diag (discarded svd.values k))
    exact (abs_of_nonneg hn).symm
```

Proof reading. Rewrite the core reconstruction as a lift through the composed isometries. Rewrite the factor product as the retained diagonal lift. Derive isometry of each composed factor. Apply the spectral and Frobenius transfer lemmas to their independently proved diagonal best-rank conclusions. For the three error formulas, use linearity of lift, norm preservation, and the diagonal tail identities. The square-root formula uses nonnegativity of the Frobenius norm. These are conclusions of the theorem, not fields of its SVD input.

Source: `formalization/SmallCoreRecompression.lean`.

Exact lines 124–141. Excerpt `small_core_endpoint`. SHA-256 in Section 15.

```
theorem small_core_optimal_recompression (L : Matrix m t ℂ) (R : Matrix n t ℂ)
    (svd : OrderedThinSVD (factorCore L R) d) (k : ℕ) :
    let Lk := recompressLeft (compactQ L) svd k
    let Rk := recompressRight (compactQ R) svd k
    BestRank spectralNorm (L*Rᴴ) (Lk*Rkᴴ) k ∧
    BestRank frobeniusNorm (L*Rᴴ) (Lk*Rkᴴ) k ∧
    spectralNorm (L*Rᴴ-Lk*Rkᴴ)=nextSingular svd.values k ∧
    frobeniusNorm (L*Rᴴ-Lk*Rkᴴ)^2=tailEnergy svd.values k ∧

    compactDim L=L.rank ∧ compactDim R=R.rank ∧
    Fintype.card (KeptColumn d k)=min d k := by
  dsimp only
  have h := recompression_optimality (compactQ L) (compactQ R)
    (compactQ_isometry L) (compactQ_isometry R) svd k
  dsimp only at h
  rw [←compact_product_reconstruction L R] at h
  exact ⟨h.1,h.2.1,h.2.2.1,h.2.2.2.1,h.2.2.2.2,
    compactDim_eq_rank L,compactDim_eq_rank R,keptColumn_card k⟩
```

Proof reading. Instantiate the preceding theorem with the compact factors constructed from the original L and R. Rewrite their lifted core as LR^*. Pair its two global optimality conclusions and exact tail errors with the proved equalities between compact dimensions and original ranks, and with the retained-column cardinality. Thus the endpoint concerns the original rectangular factor product and every ambient rank-bounded competitor.

10.8 Zero rank and full retention remain defined

Source: `formalization/RecompressionEndpoints.lean`.

Exact lines 70–74. Excerpt `full_retention`. SHA-256 in Section 15.

```
theorem recompression_full (Q : Matrix m r ℂ) (V : Matrix n s ℂ)
    {G : Matrix r s ℂ} (svd : OrderedThinSVD G d) (k : ℕ) (hk : d ≤ k) :
    recompressLeft Q svd k*(recompressRight V svd k)ᴴ = lift Q V G := by
  rw [recompressed_product,kept_all _ k hk,←lift_comp]
  exact congrArg (lift Q V) svd.reconstruction.symm
```

Proof reading. When $d \leq k$, retaining the entire value list gives the original diagonal. Rewrite the constructed product by that full-retention identity, then use the supplied SVD reconstruction under the outer lift. The separate rank-zero endpoint proves that keeping no columns gives the zero product. Empty index types avoid dummy inverse operations and support zero original factors. Repeated or zero singular values are permitted by the non-strict ordering.

10.9 The formal boundary

The ordered-SVD-data theorem proves conditional exact optimality and exact tail errors. General SVD existence, identification with the canonical Mathlib `singularValues` API, a floating-point SVD or QR algorithm, and its numerical stability are outside this formal block. Classical item 5.5 remains separately tracked, with these checked supporting results. The formal construction does not establish GPU performance, a generic dense matrix exponent, or equivalence to the supplied NumPy prototype.

11.4 Classical inputs are not folded into the 56 count

Item	Classical input	Precise present boundary
5.5	Eckart–Young–Mirsky	Ordered diagonal spectral and Frobenius best-rank bounds and isometric transfer are checked as sup- port for 5.6. General SVD existence and the canonical singular-values API theorem are not formalized here.
7.5	CG convergence	The classical energy-error estimate is supplied. The formal block proves monotonicity and replacement by a certified condition bound, rather than proving the CG algorithm or its classical convergence theorem.
8.2	Floating-point product model	Local error inequalities are supplied to exact normed ring propagation. IEEE rounding semantics and a device implementation are not independently proved.
9.1	Simultaneous spectral decomposition	Exact residual and off-diagonal certificates are proved for a supplied finite self-adjoint projector family. A general simultaneous-decomposition algorithm is not independently formalized.

11.5 Finite numerical examples

The recorded numerical mirror covers 182 factor pairs, 638 truncation cases, 3,190 arbitrary rank-bounded competitors, nine invalid-input controls and two assumption-removal controls. It uses NumPy complex128 and numerical rank thresholds. It is neither extracted nor compiled Lean and does not prove universal matrix optimality. The CPU/GPU measurements remain separate and do not automatically instantiate the complete formal fair-match signature.

11.6 Reproducible limits

The three companions share the original result keys and preserve the complete raw mathematical and formal sources. The paper-to-Lean map explains recorded hypotheses and scope. It is not an automatically checked semantic-equivalence theorem between prose, Lean, and prototype Python. No fresh CUDA correctness, device stability, timing advantage, full imported-library rebuild, or claims beyond the stated finite mathematics follow from the documentation checks.

12 Complete manuscript-result correspondence

The original manuscript numbering below is retained as a stable key across the companions. The preserved ledger has 85 numbered records, including definitions and expository entries. This map prints its 56 manuscript-proved results and four classical inputs. Source locations identify declarations. They do not claim that Lean certifies prose-to-code equivalence automatically.

12.1 2.3 — Exact evaluation

Traditional original item 2.3, current statement 2.3. Printed page 7, PDF page 13.

Recorded status. checked.

Recorded hypotheses and scope. Finite orthogonal idempotent family summing to one. Exact nonzero support, not thresholded support. Actual rectangular matrix batches are covered.

- `KomorebiPaperVIII.exact_active_evaluation`; `PacketIR.lean`, line 41.
- `KomorebiPaperVIII.exact_active_action`; `PacketIR.lean`, line 52.
- `KomorebiPaperVIII.exact_matrix_batch`; `PacketIR.lean`, line 145.

12.2 2.5 — Block composition

Traditional original item 2.5, current statement 2.5. Printed page 8, PDF page 14.

Recorded status. checked.

Recorded hypotheses and scope. Finite projector family over a ring. Relational composition gives an inclusion because nonzero path terms can cancel.

- `KomorebiPaperVIII.exact_block_composition`; `PacketIR.lean`, line 58.
- `KomorebiPaperVIII.product_support_inclusion`; `PacketIR.lean`, line 63.

12.3 2.6 — Adjoint and tensor semantics

Traditional original item 2.6, current statement 2.6. Printed page 9, PDF page 15.

Recorded status. checked.

Recorded hypotheses and scope. Adjoint identity explicitly assumes self-adjoint projectors in a star ring. Tensor identity uses actual Kronecker products of finite matrices.

- `KomorebiPaperVIII.exact_adjoint_block`; `PacketIR.lean`, line 95.
- `KomorebiPaperVIII.exact_tensor_block`; `PacketIR.lean`, line 135.

12.4 2.9 — Contract conversion

Traditional original item 2.9, current statement 2.9. Printed page 9, PDF page 15.

Recorded status. checked.

Recorded hypotheses and scope. Formal output conversion includes the actual decoding map and its declared time. Direct downstream composition is proved. This is a contract model, not independent validation of timings.

- `KomorebiPaperVIII.contract_conversion`; `SchedulingContracts.lean`, line 54.

- `KomorebiPaperVIII.direct_compressed_consumption`; `SchedulingContracts.lean`, line 62.
- `KomorebiPaperVIII.omitted_decode_understates_time`; `SchedulingContracts.lean`, line 69.

12.5 3.1 — Dense and packet application counts

Traditional original item 3.1, current statement 3.1. Printed page 10, PDF page 16.

Recorded status. checked.

Recorded hypotheses and scope. Finite scalar address and modeled multiply-accumulate event cardinalities. Two scalar operations per coefficient/right-hand side. No device instruction claim.

- `KomorebiPaperVIII.packet_storage_count`; `PacketCostModels.lean`, line 27.
- `KomorebiPaperVIII.packet_application_count`; `PacketCostModels.lean`, line 31.
- `KomorebiPaperVIII.dense_storage_count`; `PacketCostModels.lean`, line 36.
- `KomorebiPaperVIII.dense_application_count`; `PacketCostModels.lean`, line 39.

12.6 3.2 — Equal diagonal packets

Traditional original item 3.2, current statement 3.2. Printed page 10, PDF page 16.

Recorded status. checked.

Recorded hypotheses and scope. Equal widths, n = card(I)*b. Positive/nonzero denominators for real ratios. Work-ratio specialization follows from equal_bdlr_reduction at r=0.

- `KomorebiPaperVIII.equal_diagonal_storage`; `PacketCostModels.lean`, line 44.
- `KomorebiPaperVIII.equal_diagonal_work`; `PacketCostModels.lean`, line 48.
- `KomorebiPaperVIII.equal_block_reduction`; `PacketCostModels.lean`, line 87.

12.7 3.4 — BDLR application and storage

Traditional original item 3.4, current statement 3.4. Printed page 11, PDF page 17.

Recorded status. checked.

Recorded hypotheses and scope. Explicit diagonal and two thin factor address/event types; third kernel accumulates into the diagonal result. The actual algebraic action is the unchanged LowRankAlgebra.bdlr_apply theorem.

- `KomorebiPaperVIII.bdlr_storage_count`; `PacketCostModels.lean`, line 58.
- `KomorebiPaperVIII.bdlr_application_count`; `PacketCostModels.lean`, line 68.
- `KomorebiPaperVIII.equal_bdlr_storage`; `PacketCostModels.lean`, line 75.
- `KomorebiPaperVIII.equal_bdlr_work`; `PacketCostModels.lean`, line 81.
- `KomorebiPaperVIII.equal_bdlr_reduction`; `PacketCostModels.lean`, line 91.

12.8 3.6 — Streaming byte count

Traditional original item 3.6, current statement 3.6. Printed page 11, PDF page 17.

Recorded status. checked.

Recorded hypotheses and scope. One block read, one source read, target read and write per active edge, no interedge reuse. Count is of declared events.

- `KomorebiPaperVIII.streaming_value_count`; `PacketCostModels.lean`, line 102.
- `KomorebiPaperVIII.streaming_byte_count`; `PacketCostModels.lean`, line 111.

12.9 3.8 — Roofline lower bound

Traditional original item 3.8, current statement 3.8. Printed page 12, PDF page 18.

Recorded status. checked.

Recorded hypotheses and scope. Time bound assumes positive peak rates and actual capacity inequalities. Work-rate bound assumes nonnegative work, positive bytes and elapsed time. These hypotheses are explicit.

- `KomorebiPaperVIII.roofline_time_bound`; `PacketCostModels.lean`, line 118.
- `KomorebiPaperVIII.roofline_work_rate`; `PacketCostModels.lean`, line 126.

12.10 3.9 — Capacity threshold

Traditional original item 3.9, current statement 3.9. Printed page 12, PDF page 18.

Recorded status. checked.

Recorded hypotheses and scope. Dense scalar capacity equivalence uses n,M nonnegative and scalar byte size positive. BDLR natural-number storage inequality is exact; workspace memory is excluded.

- `KomorebiPaperVIII.dense_capacity_threshold`; `PacketCostModels.lean`, line 139.
- `KomorebiPaperVIII.bdlr_capacity_threshold`; `PacketCostModels.lean`, line 143.

12.11 3.10 — Materialization cost

Traditional original item 3.10, current statement 3.10. Printed page 13, PDF page 19.

Recorded status. checked.

Recorded hypotheses and scope. Explicit dense low-rank product followed by one scalar addition per output has 2*n^2*r+n^2 modeled operations. The remainder has the exact quadratic bound n^2, stronger than the displayed big-O term; no generic implementation lower bound.

- `KomorebiPaperVIII.materialization_work_count`; `PacketCostModels.lean`, line 151.
- `KomorebiPaperVIII.materialization_quadratic_remainder`; `PacketCostModels.lean`, line 156.
- `KomorebiPaperVIII.dense_storage_count`; `PacketCostModels.lean`, line 36.

12.12 4.1 — Equal block banded count

Traditional original item 4.1, current statement 4.1. Printed page 13, PDF page 19.

Recorded status. checked.

Recorded hypotheses and scope. Actual band address subtype in Fin p x Fin p. Count p*(2*w+1)-w*(w+1) proved from finite sums under w<p. Explicit stored-scalar and multiply/accumulate event types give b^2*N and 2*q*b^2*N. The manuscript substitution p=n/b additionally needs b>0 and exact divisibility. No hardware operation timing claim.

- `KomorebiPaperVIII.banded_block_count`; `BandedCount.lean`, line 73.
- `KomorebiPaperVIII.banded_storage_count`; `BandedCount.lean`, line 85.
- `KomorebiPaperVIII.banded_operation_count`; `BandedCount.lean`, line 90.

12.13 4.2 — Sparse plus low rank application

Traditional original item 4.2, current statement 4.2. Printed page 14, PDF page 20.

Recorded status. checked.

Recorded hypotheses and scope. Counts actual sparse-value and thin-factor address types, excluding sparse index metadata. Algebraic action follows from the upstream bdlr_apply identity, which does not require its D argument to be diagonal.

- `KomorebiPaperVIII.sparse_low_rank_storage_count`; `PacketCostModels.lean`, line 164.
- `KomorebiPaperVIII.sparse_low_rank_work_count`; `PacketCostModels.lean`, line 169.

12.14 4.3 — Circulant spectral representation

Traditional original item 4.3, current statement 4.3. Printed page 14, PDF page 20.

Recorded status. checked.

Recorded hypotheses and scope. Actual circulant and unitary-normalized Fourier matrix on ZMod n for every n>0. The exponential formula, both unitarity identities, exact diagonalization and two-transform application are checked. No FFT complexity or hardware execution is claimed.

- `KomorebiPaperVIII.fourier_matrix_exponential`; `CirculantFourier.lean`, line 39.
- `KomorebiPaperVIII.fourier_unitary`; `CirculantFourier.lean`, line 83.
- `KomorebiPaperVIII.circulant_spectral_representation`; `CirculantFourier.lean`, line 150.
- `KomorebiPaperVIII.circulant_fourier_application`; `CirculantFourier.lean`, line 155.

12.15 4.4 — Toeplitz circulant embedding

Traditional original item 4.4, current statement 4.4. Printed page 15, PDF page 21.

Recorded status. checked.

Recorded hypotheses and scope. Actual complex Toeplitz matrix, explicitly reversed generator of length n+n and Fin.addCases zero padding for n>0. The diagonal uses c[0]; r[0] is irrelevant. Neither symmetry nor Hermiticity is assumed.

- `KomorebiPaperVIII.toeplitz_circulant_block`; `ToeplitzEmbedding.lean`, line 28.
- `KomorebiPaperVIII.toeplitz_embedding_action`; `ToeplitzEmbedding.lean`, line 54.

- `KomorebiPaperVIII.toeplitz_generator_first_half`; `ToeplitzEmbedding.lean`, line 60.
- `KomorebiPaperVIII.toeplitz_generator_middle`; `ToeplitzEmbedding.lean`, line 64.

12.16 4.5 — Kronecker modewise application

Traditional original item 4.5, current statement 4.5. Printed page 15, PDF page 21.

Recorded status. checked.

Recorded hypotheses and scope. Actual column-major Matrix.vec and actual Kronecker products; the right factor uses transpose, not adjoint. Arithmetic and factor-storage counts are cardinalities of finite address/event types.

- `KomorebiPaperVIII.kronecker_modewise`; `StructuredTensor.lean`, line 19.
- `KomorebiPaperVIII.kronecker_modewise_work`; `StructuredTensor.lean`, line 27.
- `KomorebiPaperVIII.kronecker_factor_storage`; `StructuredTensor.lean`, line 32.

12.17 4.6 — Equal tensor factors

Traditional original item 4.6, current statement 4.6. Printed page 15, PDF page 21.

Recorded status. checked.

Recorded hypotheses and scope. Actual arbitrary-length recursive tensor matrix and slice-by-slice contraction. Exact event count 2*k*d^(k+1) and storage k*d^2; includes k=0 and d=0. Model charges two operations per multiply-accumulate.

- `KomorebiPaperVIII.tensor_dimension`; `StructuredTensor.lean`, line 51.
- `KomorebiPaperVIII.tensor_apply_correct`; `StructuredTensor.lean`, line 73.
- `KomorebiPaperVIII.tensor_modewise_work`; `StructuredTensor.lean`, line 112.
- `KomorebiPaperVIII.tensor_factor_storage`; `StructuredTensor.lean`, line 126.

12.18 4.7 — Walsh Hadamard recursion

Traditional original item 4.7, current statement 4.7. Printed page 16, PDF page 22.

Recorded status. checked.

Recorded hypotheses and scope. Recursively constructed complex Walsh matrices and actual sum/difference butterfly. Proves ordinary-transpose orthogonality, algorithm correctness and exactly N*log2(N) additions/subtractions for N=2^k, including N=1.

- `KomorebiPaperVIII.walsh_orthogonal`; `WalshTransform.lean`, line 33.
- `KomorebiPaperVIII.walsh_apply_correct`; `WalshTransform.lean`, line 60.
- `KomorebiPaperVIII.walsh_operation_count`; `WalshTransform.lean`, line 99.
- `KomorebiPaperVIII.walsh_log_operation_count`; `WalshTransform.lean`, line 115.

12.19 5.1 — Exact BDLR product

Traditional original item 5.1, current statement 5.1. Printed page 16, PDF page 22.

Recorded status. checked.

Recorded hypotheses and scope. Finite rectangular factors over a field with involution. Diagonal closure and actual correction rank are proved. No materialization or timing claim.

- `KomorebiPaperVIII.packet_diagonal_product`; `LowRankAlgebra.lean`, line 33.
- `KomorebiPaperVIII.bdlr_product`; `LowRankAlgebra.lean`, line 57.
- `KomorebiPaperVIII.bdlr_product_rank_bound`; `LowRankAlgebra.lean`, line 68.

12.20 5.2 — Rank growth in a product chain

Traditional original item 5.2, current statement 5.2. Printed page 17, PDF page 23.

Recorded status. checked.

Recorded hypotheses and scope. Actual variable-rank thin matrix factors are constructed for every length, including zero rank and the empty product. The correction matrix rank is bounded by the sum of factor widths. Packet diagonality of the base product is derived.

- `KomorebiPaperVIII.chainFactors_correct`; `LowRankChains.lean`, line 56.
- `KomorebiPaperVIII.bdlr_chain_rank_bound`; `LowRankChains.lean`, line 69.
- `KomorebiPaperVIII.packet_diagonal_chain`; `LowRankChains.lean`, line 87.

12.21 5.3 — Woodbury inversion

Traditional original item 5.3, current statement 5.3. Printed page 18, PDF page 24.

Recorded status. checked.

Recorded hypotheses and scope. Both D and I+V* D^{-1} U are units. The update is proved invertible. Ordinary matrix inverse and arbitrary right-hand-side batches. Uses Mathlib classical Woodbury identity.

- `KomorebiPaperVIII.bdlr_woodbury`; `LowRankAlgebra.lean`, line 89.
- `KomorebiPaperVIII.bdlr_update_isUnit`; `LowRankAlgebra.lean`, line 97.
- `KomorebiPaperVIII.bdlr_woodbury_solve`; `LowRankAlgebra.lean`, line 110.

12.22 5.4 — Inverse norm bound

Traditional original item 5.4, current statement 5.4. Printed page 18, PDF page 24.

Recorded status. checked.

Recorded hypotheses and scope. Real or complex matrices with the Hilbert-space L2 operator norm, including rectangular factors. Same two invertibility assumptions as 5.3.

- `KomorebiPaperVIII.bdlr_inverse_norm_bound`; `LowRankAlgebra.lean`, line 126.

12.23 5.5 — Eckart Young Mirsky theorem

Traditional original item 5.5, current statement 5.5. Printed page 18, PDF page 24.

Recorded status. external_input_with_checked_svd_data_specialization.

Recorded hypotheses and scope. Ordered diagonal spectral/Frobenius best-rank inequalities and rectangular isometric transfer are now independently checked as supporting results for 5.6. General SVD existence and a theorem phrased in the canonical Mathlib singularValues API are not formalized here. This classical entry stays separately tracked, not added to the 56 manuscript-proved count.

12.24 5.6 — Small core recompression

Traditional original item 5.6, current statement 5.6. Printed page 18, PDF page 24.

Recorded status. checked.

Recorded hypotheses and scope. Actual compact orthonormal column-space factorizations with dimensions equal to the input matrix ranks. For any supplied ordered thin SVD of the actual small core, constructs thin square-root factors with min(d,k) columns, proves rank <= k, global spectral and Frobenius optimality against every ambient competitor, and exact tail errors. No assumed optimality, tail formulas, norm invariance or rank identities. Includes zero and rank-deficient factors, k=0, k>=d and repeated singular values. SVD existence/computation, floating-point QR/SVD, and canonical Mathlib singularValues identification are not independently formalized. The supplied SVD equations are explicit hypotheses, as in the manuscript.

- `KomorebiPaperVIII.SmallCore.small_core_optimal_recompression`; `SmallCoreRecompression.lean`, line 124.
- `KomorebiPaperVIII.SmallCore.recompression_optimality`; `SmallCoreRecompression.lean`, line 91.
- `KomorebiPaperVIII.SmallCore.compact_product_reconstruction`; `SmallCoreTransfer.lean`, line 61.
- `KomorebiPaperVIII.SmallCore.diagonal_spectral_best`; `SpectralOptimality.lean`, line 120.
- `KomorebiPaperVIII.SmallCore.diagonal_frobenius_best`; `FrobeniusOptimality.lean`, line 106.

12.25 5.8 — Product chain perturbation

Traditional original item 5.8, current statement 5.8. Printed page 19, PDF page 25.

Recorded status. checked.

Recorded hypotheses and scope. Actual ordered products in a normed ring with norm-one identity. Includes the empty chain. The displayed finite sum uses perturbed suffix norms and exact prefix norms. This covers operators on nonzero normed spaces, without a commutativity assumption.

- `KomorebiPaperVIII.product_chain_perturbation`; `ProductChainError.lean`, line 148.
- `KomorebiPaperVIII.product_chain_error_bound`; `ProductChainError.lean`, line 129.

12.26 5.9 — Certified repeated recompression

Traditional original item 5.9, current statement 5.9. Printed page 20, PDF page 26.

Recorded status. checked.

Recorded hypotheses and scope. Actual left-multiplied iterates with additive post-product residuals in a normed ring. Both actual residual norms and arbitrary certified error budgets are supported, including the empty iteration.

- `KomorebiPaperVIII.repeated_recompression_bound`; `ProductChainError.lean`, line 100.
- `KomorebiPaperVIII.repeated_recompression_actual_error`; `ProductChainError.lean`, line 114.

12.27 6.1 — Path support of powers

Traditional original item 6.1, current statement 6.1. Printed page 21, PDF page 27.

Recorded status. checked.

Recorded hypotheses and scope. Recursive finite sum over active paths equals the actual block of A^n. Includes length zero explicitly.

- `KomorebiPaperVIII.power_path_expansion`; `TransferSupport.lean`, line 37.
- `KomorebiPaperVIII.power_block_zero_of_no_path`; `TransferSupport.lean`, line 74.
- `KomorebiPaperVIII.power_support_inclusion`; `TransferSupport.lean`, line 79.

12.28 6.2 — Polynomial support

Traditional original item 6.2, current statement 6.2. Printed page 21, PDF page 27.

Recorded status. checked.

Recorded hypotheses and scope. Actual finite polynomial sum in an algebra. Support contained in the union over powers, including the constant term.

- `KomorebiPaperVIII.polynomial_support_inclusion`; `TransferSupport.lean`, line 127.
- `KomorebiPaperVIII.polynomial_zero_of_no_paths`; `TransferSupport.lean`, line 142.

12.29 6.3 — Acyclic transfer nilpotence

Traditional original item 6.3, current statement 6.3. Printed page 21, PDF page 27.

Recorded status. checked.

Recorded hypotheses and scope. Absence of paths of length h+1 forces A^(h+1)=0. Also derived from a supplied strictly increasing topological level certificate. No graph-level construction algorithm is claimed.

- `KomorebiPaperVIII.nilpotent_of_path_bound`; `TransferSupport.lean`, line 86.
- `KomorebiPaperVIII.nilpotent_of_topological_levels`; `TransferSupport.lean`, line 109.

12.30 6.5 — Level schedule for a triangular solve

Traditional original item 6.5, current statement 6.5. Printed page 22, PDF page 28.

Recorded status. checked.

Recorded hypotheses and scope. Actual well-founded forward substitution and stage evaluator in dependent, possibly unequal block spaces. Finite acyclic graph, invertible local diagonal maps, and arbitrary linear edge transfers. No precomputed solution or topological schedule is assumed. Stages read only predecessors and solve the original block equations at canonical depth.

- `KomorebiPaperVIII.DAG.Graph.solve_correct`; `TriangularSolve.lean`, line 38.
- `KomorebiPaperVIII.DAG.Graph.solve_unique`; `TriangularSolve.lean`, line 46.
- `KomorebiPaperVIII.DAG.Graph.triangular_bijective`; `TriangularSolve.lean`, line 65.
- `KomorebiPaperVIII.DAG.Graph.stagedSolve_correct_through`; `TriangularSolve.lean`, line 91.
- `KomorebiPaperVIII.DAG.Graph.level_schedule_solves`; `TriangularSolve.lean`, line 112.

12.31 6.6 — Sequential depth

Traditional original item 6.6, current statement 6.6. Printed page 22, PDF page 28.

Recorded status. checked.

Recorded hypotheses and scope. Canonical predecessor-max levels are constructed from acyclicity through strict ancestor-cardinality decrease. For nonempty finite graphs, attained maximum equals one plus longest edge-path length. Empty graph has depth zero. This is an ideal unit-task schedule, not a hardware timing theorem.

- `KomorebiPaperVIII.DAG.Graph.level_attained`; `GraphSchedules.lean`, line 101.
- `KomorebiPaperVIII.DAG.Graph.path_length_le_depth`; `GraphSchedules.lean`, line 156.
- `KomorebiPaperVIII.DAG.Graph.depth_attained`; `GraphSchedules.lean`, line 164.
- `KomorebiPaperVIII.DAG.Graph.empty_depth`; `GraphSchedules.lean`, line 177.

12.32 6.7 — Inverse support lies in the transitive closure

Traditional original item 6.7, current statement 6.7. Printed page 23, PDF page 29.

Recorded status. checked.

Recorded hypotheses and scope. Actual reachable packet subspace in a finite-dimensional algebra is invariant. A left inverse makes the restricted forward map injective, hence surjective, yielding inverse invariance. Actual nonsingular matrix inverse specialization. Reachability is reflexive: zero-length paths are included. No inverse-support hypothesis is assumed.

- `KomorebiPaperVIII.inverse_block_zero_of_no_path`; `InverseSupport.lean`, line 94.
- `KomorebiPaperVIII.inverse_support_inclusion`; `InverseSupport.lean`, line 102.
- `KomorebiPaperVIII.matrix_inverse_support`; `InverseSupport.lean`, line 116.

12.33 6.8 — Schur support inclusion

Traditional original item 6.8, current statement 6.8. Printed page 23, PDF page 29.

Recorded status. checked.

Recorded hypotheses and scope. Actual rectangular retained-hidden factors and nonsingular hidden matrix inverse. Nonzero Schur block implies a direct retained edge or nonzero entrance, reachable hidden path (possibly zero length), and nonzero exit. Only support inclusion is asserted; cancellation may remove a permitted block.

- `KomorebiPaperVIII.schur_correction_expansion`; `SchurSupport.lean`, line 25.
- `KomorebiPaperVIII.schur_correction_support`; `SchurSupport.lean`, line 33.
- `KomorebiPaperVIII.schur_support_inclusion`; `SchurSupport.lean`, line 57.
- `KomorebiPaperVIII.schur_zero_of_no_route`; `SchurSupport.lean`, line 76.

12.34 7.2 — Invariant packet Krylov decomposition

Traditional original item 7.2, current statement 7.2. Printed page 24, PDF page 30.

Recorded status. checked.

Recorded hypotheses and scope. Actual bounded linear maps and spans of finite power orbits. Commutation with the complete finite projector family gives the power expansion and Krylov inclusion. Local spaces lie in the actual projector ranges and their sum is direct. No equality of the global and local Krylov spaces is asserted.

- `KomorebiPaperVIII.invariant_packet_power_expansion`; `KrylovPackets.lean`, line 76.
- `KomorebiPaperVIII.invariant_packet_krylov`; `KrylovPackets.lean`, line 89.
- `KomorebiPaperVIII.local_krylov_direct`; `KrylovPackets.lean`, line 131.

12.35 7.3 — Approximate packet Krylov bound

Traditional original item 7.3, current statement 7.3. Printed page 24, PDF page 30.

Recorded status. checked.

Recorded hypotheses and scope. Positive integer power, actual operator norm, and actual Metric.infDist to the sum of local Krylov spaces. Membership of the comparison vector D^j v is derived from packet diagonality. The power estimate also allows a trivial normed ring.

- `KomorebiPaperVIII.approximate_packet_power_bound`; `KrylovPackets.lean`, line 170.
- `KomorebiPaperVIII.approximate_packet_krylov_distance`; `KrylovPackets.lean`, line 183.

12.36 7.4 — Block Jacobi condition bound

Traditional original item 7.4, current statement 7.4. Printed page 25, PDF page 31.

Recorded status. checked.

Recorded hypotheses and scope. Nonempty finite complex matrices, D positive definite and D+K positive definite. D^(-1/2) is the actual inverse of CFC.sqrt D. With ||D^(-1/2) K D^(-1/2)||_2 <= eta <1, proves the condition product ||B||_2*||B^(-1)||_2 <=(1+eta)/(1-eta). Norms are the Euclidean operator norm. The inverse estimate does not require a separately assumed Hermitian perturbation.

- `KomorebiPaperVIII.invSqrt_isUnit`; `BlockJacobi.lean`, line 59.

- `KomorebiPaperVIII.invSqrt_normalizes`; `BlockJacobi.lean`, line 65.
- `KomorebiPaperVIII.normalized_decomposition`; `BlockJacobi.lean`, line 80.
- `KomorebiPaperVIII.block_jacobi_condition`; `BlockJacobi.lean`, line 87.

12.37 7.5 — Preconditioned conjugate gradient convergence

Traditional original item 7.5, current statement 7.5. Printed page 25, PDF page 31.

Recorded status. external_input_not_independently_formalized.

Recorded hypotheses and scope. Classical input tracked separately; see the boundary discussion.

12.38 7.6 — Certified packet preconditioning

Traditional original item 7.6, current statement 7.6. Printed page 25, PDF page 31.

Recorded status. checked.

Recorded hypotheses and scope. Monotonicity of the actual sqrt-based CG factor and its value at the normalized matrix condition number. Propagates an explicit classical energy-error estimate to the certified eta bound. Classical input 7.5 (CG convergence algorithm theorem) is not reproved or silently assumed as a new axiom.

- `KomorebiPaperVIII.matrix_condition_ge_one`; `BlockJacobi.lean`, line 97.
- `KomorebiPaperVIII.cgFactor_mono`; `BlockJacobi.lean`, line 106.
- `KomorebiPaperVIII.certified_packet_factor`; `BlockJacobi.lean`, line 126.
- `KomorebiPaperVIII.certified_energy_error`; `BlockJacobi.lean`, line 134.

12.39 8.1 — Packet perturbation certificate

Traditional original item 8.1, current statement 8.1. Printed page 26, PDF page 32.

Recorded status. checked.

Recorded hypotheses and scope. Actual continuous linear maps and their operator norm. Source support is assumed only for errors, a weaker sufficient hypothesis. Vector and uniform operator bounds. Not an IEEE/CUDA implementation verification.

- `KomorebiPaperVIII.packet_perturbation_bound`; `PacketPerturbation.lean`, line 35.
- `KomorebiPaperVIII.packet_relative_perturbation_bound`; `PacketPerturbation.lean`, line 42.
- `KomorebiPaperVIII.packet_operator_perturbation_bound`; `PacketPerturbation.lean`, line 51.
- `KomorebiPaperVIII.contractive_packet_operator_bound`; `PacketPerturbation.lean`, line 59.

12.40 8.2 — Floating point matrix product model

Traditional original item 8.2, current statement 8.2. Printed page 27, PDF page 33.

Recorded status. external_input_not_independently_formalized.

Recorded hypotheses and scope. Classical input tracked separately; see the boundary discussion.

12.41 8.3 — Mixed precision product chain

Traditional original item 8.3, current statement 8.3. Printed page 27, PDF page 33.

Recorded status. checked.

Recorded hypotheses and scope. Stagewise packet bounds are uniform operator-norm certificates on a nonzero normed space, not vector-specific bounds reused as operator norms. The exact-product perturbation theorem propagates those certificates. Vector error follows by multiplying the operator bound by the input norm.

- `KomorebiPaperVIII.mixed_precision_product_chain`; `ProductChainError.lean`, line 164.
- `KomorebiPaperVIII.chain_action_error`; `ProductChainError.lean`, line 180.

12.42 8.4 — Continuous precision allocation

Traditional original item 8.4, current statement 8.4. Printed page 27, PDF page 33.

Recorded status. checked.

Recorded hypotheses and scope. Finite nonempty edge set, strictly positive sensitivities, costs, and budget. Actual sum c*log(1/eps). Feasibility, global optimality, strict inequality away from formula, and unique minimizer. No KKT or convexity result is assumed.

- `KomorebiPaperVIII.optimal_tolerance_feasible`; `ContinuousPrecision.lean`, line 48.
- `KomorebiPaperVIII.precision_allocation_optimal`; `ContinuousPrecision.lean`, line 80.
- `KomorebiPaperVIII.precision_allocation_strict`; `ContinuousPrecision.lean`, line 100.
- `KomorebiPaperVIII.continuous_precision_unique_minimizer`; `ContinuousPrecision.lean`, line 131.

12.43 8.5 — Clipped precision allocation

Traditional original item 8.5, current statement 8.5. Printed page 28, PDF page 34.

Recorded status. checked.

Recorded hypotheses and scope. Finite nonempty set; strictly positive sensitivities, costs and caps; 0<budget<=total capped tolerance. Existence by IVT; global strict supporting-log inequality and unique minimizing vector. Unique positive multiplier only strictly below the maximum; endpoint nonuniqueness checked.

- `KomorebiPaperVIII.clipped_scale_exists`; `ClippedPrecision.lean`, line 74.
- `KomorebiPaperVIII.clipped_unique_minimizer`; `ClippedPrecision.lean`, line 211.
- `KomorebiPaperVIII.clipped_multiplier_exists_unique`; `ClippedPrecision.lean`, line 250.
- `KomorebiPaperVIII.clipped_endpoint_nonunique_multiplier`; `ClippedPrecision.lean`, line 244.

12.44 8.7 — Exact discrete precision program

Traditional original item 8.7, current statement 8.7. Printed page 29, PDF page 35.

Recorded status. checked.

Recorded hypotheses and scope. Independent legal assignments choose one listed option per edge. Nonnegative integer weights and exact ordered-field costs. Exact-weight states plus the final budget scan give the optimum with attainment or exact infeasibility. The residual-budget subtraction is

guarded. StoredBudgetCompiler proves the actual array-backed implementation equal to this specification.

- `KomorebiPaperVIII.BudgetDP.discrete_precision_program`; `DiscretePrecision.lean`, line 96.
- `KomorebiPaperVIII.BudgetDP.discreteBudget_some_iff`; `DiscretePrecision.lean`, line 110.
- `KomorebiPaperVIII.BudgetDP.discreteBudget_none_iff`; `DiscretePrecision.lean`, line 124.
- `KomorebiPaperVIII.BudgetDP.storedDiscreteBudget_correct`; `StoredBudgetCompiler.lean`, line 186.

12.45 9.1 — Simultaneous spectral decomposition

Traditional original item 9.1, current statement 9.1. Printed page 30, PDF page 36.

Recorded status. external_input_not_independently_formalized.

Recorded hypotheses and scope. Classical input tracked separately; see the boundary discussion.

12.46 9.2 — Exact block discovery certificate

Traditional original item 9.2, current statement 9.2. Printed page 30, PDF page 36.

Recorded status. checked.

Recorded hypotheses and scope. Actual finite complex matrices and arbitrary complete orthogonal projector family, not only standard coordinate projectors. Hilbert-Schmidt orthogonality via adjoint products and cyclic trace proves the squared Frobenius residual identity. Separate Euclidean operator-norm triangle inequality certificate. This certifies a supplied packet system, not autonomous discovery.

- `KomorebiPaperVIII.compression_residual`; `DiscoveryCertificate.lean`, line 49.
- `KomorebiPaperVIII.block_trace_orthogonal`; `DiscoveryCertificate.lean`, line 54.
- `KomorebiPaperVIII.discovery_frobenius_certificate`; `DiscoveryCertificate.lean`, line 126.
- `KomorebiPaperVIII.discovery_operator_certificate`; `DiscoveryCertificate.lean`, line 144.

12.47 9.4 — Exact Lagrangian packet compiler

Traditional original item 9.4, current statement 9.4. Printed page 31, PDF page 37.

Recorded status. checked.

Recorded hypotheses and scope. Arbitrary finite branching rooted trees, independent inductively defined cuts. Returned cut attains the recurrence and beats every legal cut. Generic ordered field covers rationals and reals. No universal discovery/approximation claim.

- `KomorebiPaperVIII.CandidateTree.exact_tree_compiler`; `ExactTreeCompiler.lean`, line 79.
- `KomorebiPaperVIII.CandidateTree.compile_attains`; `ExactTreeCompiler.lean`, line 69.
- `KomorebiPaperVIII.CandidateTree.exact_lagrangian_compiler`; `ExactTreeCompiler.lean`, line 102.

12.48 9.5 — Shared compilation for an operator family

Traditional original item 9.5, current statement 9.5. Printed page 31, PDF page 37.

Recorded status. checked.

Recorded hypotheses and scope. Exact weighted family aggregation at pruning level including setup and split overhead. Proved even without sign restrictions; intended application uses nonnegative weights.

- `KomorebiPaperVIII.CandidateTree.cutValue_weighted_family`; `ExactTreeCompiler.lean`, line 113.
- `KomorebiPaperVIII.CandidateTree.shared_family_compiler`; `ExactTreeCompiler.lean`, line 125.

12.49 9.6 — Monotone Lagrangian frontier

Traditional original item 9.6, current statement 9.6. Printed page 32, PDF page 38.

Recorded status. checked.

Recorded hypotheses and scope. Any two optimal cuts, 0 <= lambda1 < lambda2; error nonincreasing and cost nondecreasing. Optimality is discharged by the constructive compiler theorem for its returned cuts.

- `KomorebiPaperVIII.CandidateTree.monotone_lagrangian_frontier`; `ExactTreeCompiler.lean`, line 142.

12.50 9.7 — Supported Pareto points

Traditional original item 9.7, current statement 9.7. Printed page 32, PDF page 38.

Recorded status. checked.

Recorded hypotheses and scope. Positive scalarization parameter. Every true optimum is undominated. TreeCompilerUpdates.unsupported_pareto_example supplies the rational three-point unsupported-frontier inequality. Quantized-budget compiler remains unformalized.

- `KomorebiPaperVIII.CandidateTree.positive_lagrangian_pareto`; `ExactTreeCompiler.lean`, line 157.

12.51 9.8 — Quantized budget dynamic program

Traditional original item 9.8, current statement 9.8. Printed page 33, PDF page 39.

Recorded status. checked.

Recorded hypotheses and scope. The actual candidate tree and independent Cut type from the previous block, with arbitrary nonempty finite branching. Min-plus convolution over integer weights proves lower bounds, attainment, and infeasibility. StoredBudgetCompiler certifies the actual cached array-backed output. The implementation returns the minimum cost, not a backtracked cut.

- `KomorebiPaperVIII.CandidateTree.budgetTable_correct`; `QuantizedTreeCompiler.lean`, line 36.
- `KomorebiPaperVIII.CandidateTree.quantized_budget_compiler`; `QuantizedTreeCompiler.lean`, line 91.
- `KomorebiPaperVIII.CandidateTree.compileBudget_some_iff`; `QuantizedTreeCompiler.lean`, line 107.
- `KomorebiPaperVIII.CandidateTree.compileBudget_none_iff`; `QuantizedTreeCompiler.lean`, line 122.
- `KomorebiPaperVIII.CandidateTree.storedBudget_minimum`; `StoredBudgetCompiler.lean`, line 147.

12.52 9.9 — Pseudo polynomial complexity

Traditional original item 9.9, current statement 9.9. Printed page 33, PDF page 39.

Recorded status. checked.

Recorded hypotheses and scope. Array-backed tables cache child results. Concrete convolution candidate indices have at most (B+1)^2 elements. The declared unit-cost tabulation model is bounded by nodeCount*(3*(B+1)+(B+1)^2). Root minimum scan is an additional linear pass. This is pseudo-polynomial in numeric B and does not count exact-arithmetic bit complexity, compiler internals, or hardware instructions.

- `KomorebiPaperVIII.CandidateTree.merge_trial_count`; `StoredBudgetCompiler.lean`, line 222.
- `KomorebiPaperVIII.CandidateTree.merge_trial_bound`; `StoredBudgetCompiler.lean`, line 226.
- `KomorebiPaperVIII.CandidateTree.tabulation_pseudopolynomial`; `StoredBudgetCompiler.lean`, line 256.

12.53 9.11 — Compiler stability

Traditional original item 9.11, current statement 9.11. Printed page 33, PDF page 39.

Recorded status. checked.

Recorded hypotheses and scope. Actual solved keep/split scores satisfy strict half-gap inequalities at every internal node. Entire returned cut is unchanged. Ties cannot satisfy these strict hypotheses; no robustness at ties is claimed.

- `KomorebiPaperVIII.CandidateTree.half_gap_order`; `TreeCompilerUpdates.lean`, line 18.
- `KomorebiPaperVIII.CandidateTree.compiler_stability`; `TreeCompilerUpdates.lean`, line 45.

12.54 9.12 — Local recompilation

Traditional original item 9.12, current statement 9.12. Printed page 34, PDF page 40.

Recorded status. checked.

Recorded hypotheses and scope. Explicit one-hole context with cached sibling values. Replacing a subtree models localized data changes. Cache validity is constructed by refresh, not the new optimum. updateValue reads only new subtree score and caches on ancestor frames. Exact new global optimum and attaining cut proved.

- `KomorebiPaperVIII.CandidateTree.CachedContext.refresh_valid`; `TreeCompilerUpdates.lean`, line 95.
- `KomorebiPaperVIII.CandidateTree.CachedContext.updateValue_correct`; `TreeCompilerUpdates.lean`, line 109.
- `KomorebiPaperVIII.CandidateTree.CachedContext.sibling_tree_unchanged`; `TreeCompilerUpdates.lean`, line 128.
- `KomorebiPaperVIII.CandidateTree.CachedContext.sibling_value_unchanged`; `TreeCompilerUpdates.lean`, line 134.
- `KomorebiPaperVIII.CandidateTree.CachedContext.local_recompilation`; `TreeCompilerUpdates.lean`, line 142.

12.55 10.2 — Launch reduction by shape

Traditional original item 10.2, current statement 10.2. Printed page 35, PDF page 41.

Recorded status. checked.

Recorded hypotheses and scope. Finite grouping by complete shape signature, partition/fiberwise sum equals original output and work. One launch per active class is a backend capability assumption, not verified CUDA code.

- `KomorebiPaperVIII.shape_launch_count`; `SchedulingContracts.lean`, line 80.
- `KomorebiPaperVIII.grouped_execution_output`; `SchedulingContracts.lean`, line 89.
- `KomorebiPaperVIII.grouped_execution_work`; `SchedulingContracts.lean`, line 95.

12.56 10.3 — Acyclic schedule depth

Traditional original item 10.3, current statement 10.3. Printed page 35, PDF page 41.

Recorded status. checked.

Recorded hypotheses and scope. Finite acyclic task graph, unit positive-integer stages, dependency precedence, and unlimited concurrency. Constructed canonical level schedule is pointwise earliest and has minimal makespan; its depth is attained by an actual path when nonempty. Empty graph depth is zero. No weighted-task/resource-limited scheduling claim.

- `KomorebiPaperVIII.DAG.Graph.level_valid`; `GraphSchedules.lean`, line 126.
- `KomorebiPaperVIII.DAG.Graph.level_minimal`; `GraphSchedules.lean`, line 129.
- `KomorebiPaperVIII.DAG.Graph.optimal_depth`; `GraphSchedules.lean`, line 150.
- `KomorebiPaperVIII.DAG.Graph.depth_attained`; `GraphSchedules.lean`, line 164.
- `KomorebiPaperVIII.DAG.Graph.same_level_independent`; `GraphSchedules.lean`, line 181.
- `KomorebiPaperVIII.DAG.Graph.empty_depth`; `GraphSchedules.lean`, line 177.

12.57 10.4 — Amortization threshold

Traditional original item 10.4, current statement 10.4. Printed page 35, PDF page 41.

Recorded status. checked.

Recorded hypotheses and scope. Actual declared setup+R*candidate vs R*baseline inequality. Positive per-use advantage; setup nonnegative for smallest natural reuse floor+1. Equality is break-even, not profitability.

- `KomorebiPaperVIII.amortization_threshold`; `SchedulingContracts.lean`, line 101.
- `KomorebiPaperVIII.no_amortization`; `SchedulingContracts.lean`, line 107.
- `KomorebiPaperVIII.integer_amortization_threshold`; `SchedulingContracts.lean`, line 117.
- `KomorebiPaperVIII.minimum_reuse_attains`; `SchedulingContracts.lean`, line 125.

12.58 10.5 — Graph replay threshold

Traditional original item 10.5, current statement 10.5. Printed page 35, PDF page 41.

Recorded status. checked.

Recorded hypotheses and scope. Capture plus repeated replay vs repeated ordinary execution under replay<ordinary. Pure timing-model identity, not new GPU data.

- `KomorebiPaperVIII.graph_replay_threshold`; `SchedulingContracts.lean`, line 137.

12.59 10.6 — Materialization threshold

Traditional original item 10.6, current statement 10.6. Printed page 36, PDF page 42.

Recorded status. checked.

Recorded hypotheses and scope. Nonnegative materialization cost and reuse count. Strict profitability iff explicit per-use time is lower and reuse exceeds the ratio.

- `KomorebiPaperVIII.materialization_threshold`; `SchedulingContracts.lean`, line 142.

12.60 11.3 — Fair matching is an equivalence relation

Traditional original item 11.3, current statement 11.3. Printed page 36, PDF page 42.

Recorded status. checked.

Recorded hypotheses and scope. Equality of complete case, output, correctness reference, and timing-scope metadata. No inference of actual timing accuracy from matching metadata.

- `KomorebiPaperVIII.fair_match_iff_eq`; `SchedulingContracts.lean`, line 32.
- `KomorebiPaperVIII.fair_matching_equivalence`; `SchedulingContracts.lean`, line 40.

13 All named theorem and construction audits

The saved inventory contains 458 names: 392 theorems and 66 additional construction audits. The following catalog resolves namespaces from active source and records every audited name, its declaration kind, and its line. Theorem names include supporting lemmas and scope controls. Construction audits inspect transitive axioms of definitions, abbreviations, or structures. They are counted separately. The full source and the individual saved axiom sets are preserved in the accompanying files.

13.1 BandedCount: 9 theorems; 4 construction audits

Source: `formalization/BandedCount.lean`.

Audited declaration	Kind; line
`KomorebiPaperVIII.bandCount_card`	theorem; 24
`KomorebiPaperVIII.finite_prefix_count`	theorem; 27
`KomorebiPaperVIII.bandCount_succ`	theorem; 38
`KomorebiPaperVIII.bandCount_full`	theorem; 50
`KomorebiPaperVIII.bandCount_balance`	theorem; 58
`KomorebiPaperVIII.banded_block_count`	theorem; 73
`KomorebiPaperVIII.banded_storage_count`	theorem; 85
`KomorebiPaperVIII.banded_operation_count`	theorem; 90
`KomorebiPaperVIII.banded_diagonal_case`	theorem; 96
`KomorebiPaperVIII.BandedAddress`	abbrev; 17
`KomorebiPaperVIII.BandedStorage`	abbrev; 80
`KomorebiPaperVIII.BandedOperation`	abbrev; 83
`KomorebiPaperVIII.bandCount`	def; 20

13.2 BlockJacobi: 12 theorems; 3 construction audits

Source: `formalization/BlockJacobi.lean`.

Audited declaration	Kind; line
`KomorebiPaperVIII.inverse_near_one_bound`	theorem; 20
`KomorebiPaperVIII.near_one_condition_bound`	theorem; 37
`KomorebiPaperVIII.invSqrt_isUnit`	theorem; 59
`KomorebiPaperVIII.invSqrt_normalizes`	theorem; 65
`KomorebiPaperVIII.normalized_decomposition`	theorem; 80
`KomorebiPaperVIII.block_jacobi_condition`	theorem; 87
`KomorebiPaperVIII.matrix_condition_ge_one`	theorem; 97
`KomorebiPaperVIII.cgFactor_mono`	theorem; 106
`KomorebiPaperVIII.cgFactor_nonneg`	theorem; 114
`KomorebiPaperVIII.cgFactor_lt_one`	theorem; 119
`KomorebiPaperVIII.certified_packet_factor`	theorem; 126
`KomorebiPaperVIII.certified_energy_error`	theorem; 134
`KomorebiPaperVIII.invSqrt`	def; 55
`KomorebiPaperVIII.matrixCondition`	def; 57
`KomorebiPaperVIII.cgFactor`	def; 104

13.3 BoundaryChecks: 6 theorems; 0 construction audits

Source: `formalization/BoundaryChecks.lean`.

Audited declaration	Kind; line
`KomorebiPaperVIII.cancellation_square_zero`	theorem; 29
`KomorebiPaperVIII.cancellation_block_nonzero`	theorem; 34
`KomorebiPaperVIII.paths_can_cancel`	theorem; 42
`KomorebiPaperVIII.positive_allocation_budget`	theorem; 52
`KomorebiPaperVIII.no_positive_allocation_nonpositive_budget`	theorem; 58
`KomorebiPaperVIII.one_edge_zero_budget_infeasible`	theorem; 66

13.4 BudgetConvolution: 10 theorems; 0 construction audits

Source: `formalization/BudgetConvolution.lean`.

Audited declaration	Kind; line
`KomorebiPaperVIII.BudgetDP.minimum_congr`	theorem; 50
`KomorebiPaperVIII.BudgetDP.choose_correct`	theorem; 57
`KomorebiPaperVIII.BudgetDP.add_correct`	theorem; 78
`KomorebiPaperVIII.BudgetDP.bestOver_correct`	theorem; 98
`KomorebiPaperVIII.BudgetDP.convolution_correct`	theorem; 112
`KomorebiPaperVIII.BudgetDP.singletonTable_correct`	theorem; 136
`KomorebiPaperVIII.BudgetDP.combine_correct`	theorem; 148
`KomorebiPaperVIII.BudgetDP.withinBudget_correct`	theorem; 188
`KomorebiPaperVIII.BudgetDP.minimum_some_iff`	theorem; 197
`KomorebiPaperVIII.BudgetDP.minimum_none_iff`	theorem; 208

13.5 CirculantFourier: 13 theorems; 1 construction audits

Source: `formalization/CirculantFourier.lean`.

Audited declaration	Kind; line
`KomorebiPaperVIII.fourier_scale_normalization`	theorem; 22
`KomorebiPaperVIII.fourier_scale_sqrt`	theorem; 33
`KomorebiPaperVIII.fourier_matrix_exponential`	theorem; 39
`KomorebiPaperVIII.fourier_action`	theorem; 49
`KomorebiPaperVIII.fourier_adjoint_entry`	theorem; 59
`KomorebiPaperVIII.fourier_adjoint_action`	theorem; 66
`KomorebiPaperVIII.fourier_unitary`	theorem; 83
`KomorebiPaperVIII.dft_circulant`	theorem; 105
`KomorebiPaperVIII.fourier_circulant_intertwine`	theorem; 128
`KomorebiPaperVIII.circulant_spectral_dft`	theorem; 138
`KomorebiPaperVIII.normalized_fourier_eigenvalues`	theorem; 145
`KomorebiPaperVIII.circulant_spectral_representation`	theorem; 150
`KomorebiPaperVIII.circulant_fourier_application`	theorem; 155

Audited declaration	Kind; line
KomorebiPaperVIII.fourierMatrix	def; 19

13.6 ClippedPrecision: 17 theorems; 2 construction audits

Source: formalization/ClippedPrecision.lean.

Audited declaration	Kind; line
KomorebiPaperVIII.clipped_positive	theorem; 29
KomorebiPaperVIII.clipped_total_continuous	theorem; 34
KomorebiPaperVIII.clipped_total_mono	theorem; 38
KomorebiPaperVIII.clipped_total_zero	theorem; 47
KomorebiPaperVIII.saturation_scale_positive	theorem; 54
KomorebiPaperVIII.saturation_scale_attains	theorem; 60
KomorebiPaperVIII.clipped_scale_exists	theorem; 74
KomorebiPaperVIII.clipped_total_strict_below_cap	theorem; 95
KomorebiPaperVIII.clipped_scale_unique	theorem; 116
KomorebiPaperVIII.clipped_supporting_inequality	theorem; 131
KomorebiPaperVIII.clipped_relative_sum_le_zero	theorem; 149
KomorebiPaperVIII.clipped_allocation_optimal	theorem; 165
KomorebiPaperVIII.clipped_allocation_strict	theorem; 182
KomorebiPaperVIII.clipped_unique_minimizer	theorem; 211
KomorebiPaperVIII.clipped_multiplier_formula	theorem; 236
KomorebiPaperVIII.clipped_endpoint_nonunique_multiplier	theorem; 244
KomorebiPaperVIII.clipped_multiplier_exists_unique	theorem; 250
KomorebiPaperVIII.clippedTolerance	def; 19
KomorebiPaperVIII.saturationScale	def; 52

13.7 CompactRangeFactors: 7 theorems; 5 construction audits

Source: formalization/CompactRangeFactors.lean.

Audited declaration	Kind; line
KomorebiPaperVIII.SmallCore.compactDim_eq_rank	theorem; 30
KomorebiPaperVIII.SmallCore.compactQ_apply	theorem; 37
KomorebiPaperVIII.SmallCore.compactQ_isometry	theorem; 42
KomorebiPaperVIII.SmallCore.compact_factorization	theorem; 51
KomorebiPaperVIII.SmallCore.compactR_is_compression	theorem; 60
KomorebiPaperVIII.SmallCore.compactR_full_row_rank	theorem; 67
KomorebiPaperVIII.SmallCore.compact_rank_zero	theorem; 77
KomorebiPaperVIII.SmallCore.columnBasis	def; 19
KomorebiPaperVIII.SmallCore.columnSpace	def; 16
KomorebiPaperVIII.SmallCore.compactDim	def; 18
KomorebiPaperVIII.SmallCore.compactQ	def; 22
KomorebiPaperVIII.SmallCore.compactR	def; 25

13.8 CompactTruncation: 5 theorems; 2 construction audits

Source: `formalization/CompactTruncation.lean`.

Audited declaration	Kind; line
`KomorebiPaperVIII.SmallCore.keptColumn_card`	theorem; 16
`KomorebiPaperVIII.SmallCore.rootKept_tail_zero`	theorem; 23
`KomorebiPaperVIII.SmallCore.drop_zero_columns`	theorem; 31
`KomorebiPaperVIII.SmallCore.rootMask_square`	theorem; 46
`KomorebiPaperVIII.SmallCore.thin_factor_product`	theorem; 53
`KomorebiPaperVIII.SmallCore.KeptColumn`	abbrev; 14
`KomorebiPaperVIII.SmallCore.rootMask`	def; 19

13.9 ContinuousPrecision: 9 theorems; 1 construction audits

Source: `formalization/ContinuousPrecision.lean`.

Audited declaration	Kind; line
`KomorebiPaperVIII.total_cost_positive`	theorem; 27
`KomorebiPaperVIII.optimal_tolerance_positive`	theorem; 31
`KomorebiPaperVIII.optimal_tolerance_budget`	theorem; 36
`KomorebiPaperVIII.optimal_tolerance_feasible`	theorem; 48
`KomorebiPaperVIII.relative_budget_identity`	theorem; 54
`KomorebiPaperVIII.precision_objective_difference`	theorem; 68
`KomorebiPaperVIII.precision_allocation_optimal`	theorem; 80
`KomorebiPaperVIII.precision_allocation_strict`	theorem; 100
`KomorebiPaperVIII.continuous_precision_unique_minimizer`	theorem; 131
`KomorebiPaperVIII.optimalTolerance`	def; 21

13.10 DiagonalTruncation: 9 theorems; 6 construction audits

Source: `formalization/DiagonalTruncation.lean`.

Audited declaration	Kind; line
`KomorebiPaperVIII.SmallCore.kept_nonneg`	theorem; 24
`KomorebiPaperVIII.SmallCore.discarded_nonneg`	theorem; 27
`KomorebiPaperVIII.SmallCore.diagonal_residual`	theorem; 30

14 Dependencies and source identities

Both public imports and import-all commands contribute to this graph. Import-all exposes implementation details needed by downstream proofs in these source modules. Each identity below is checked against the corresponding saved compiler record and log. The runtime and imported Mathlib corpus are dependencies of the inherited evidence, rather than newly rechecked results.

14.1 Direct local dependencies

TriangularSolve

15 Exact excerpt register

Each selection is a contiguous block of the unchanged active source, retaining the declaration and proof. Module-level variables and type classes remain in force. The teaching chapters state the relevant context. The printed code applies a font fallback for the one unavailable monospaced glyph. The accompanying `.lean.txt` files preserve the raw UTF-8 bytes without substitutions.

Euler Congruences

The formal companion to Chapter IX explains the declared hypotheses, theorem correspondences and evidence boundaries.

IN THIS COMPANION

Formal companion 2221

Return to Chapter IX

Reading scope

This guide records the formal coverage of the Euler chapter and teaches the retained arithmetic, finite obstruction, polynomial tower, quantitative deformation, and analytic regularity proofs. The opening chapter maps the strengthened congruences to their existing Lean endpoints and identifies the new proofs that remain to be formalized. The complete original teaching chapters, exact source excerpts, and catalog of named sources follow.

The formal evidence consists of retained compiler records and matching source identities. The factorial and mixed-difference theorems have written proofs in the main text but no compiled Lean endpoint. Static source checks and finite computations do not replace a kernel check.

1 The strengthened Euler chapter and its exact formal coverage

The chapter combines Nishibuchi's conjecture, the four-packet theory at every row, and stronger written congruences. The capstone, step-sensitive four-packet bound, exact first-difference periods and isometry have Lean sources and compiler records. General prime-power closure, mixed factorial estimates, exact higher-order laws and Taylor radii have mathematical proofs but no compiled Lean endpoint.

The distinction is attached to claims, rather than to whole documents. A new proof may include a previously formalized special case. Conversely, an inherited endpoint about a polynomial analytic graph does not certify the new Euler interpolation radius merely because both use p-adic analysis. The tables and contracts below identify the actual overlap and the remaining work.

1.1 One normalization for the chapter and the guide

For a positive modulus N and an address $0 \le j < N$, define

$$G_{N,j}(t) = j! \sum_{n \ge 0} \frac{t^{Nn}}{(Nn+j)!}, \qquad G_{N,j}(t)^{-1} = \sum_{n \ge 0} C_{N,j}(n) \frac{t^{Nn}}{(Nn)!}.$$

The constant coefficient of both normalized series is one. The original generalized Euler number at degree Nn is

$$E_{Nn}^{(N,j)} = j!\, C_{N,j}(n).$$

Thus `Congruential.coeff N j n` corresponds to $C_{N,j}(n)$ and `Congruential.unnormalized N j n` corresponds to $E_{Nn}^{(N,j)}$. The source `NishibuchiCompletion.generalizedEuler N hN j d` instead uses the literal Euler degree d. Its theorem `generalizedEuler_at_packet` is the bridge between these indices.

Write $\Delta_H f(n) = f(n+H) - f(n)$. The source `Mahler.difference H k f n` is the homogeneous difference $\Delta_H^k f(n)$. A mixed difference applies several possibly unequal steps. Existing homogeneous endpoints cannot be substituted for a mixed endpoint without a proof relating those operators.

The notation $v_p(0) = +\infty$ makes lower bounds zero safe on paper. In the sources, `GlobalEulerBoundary.precision p r x` supplies the corresponding zero-safe rational predicate. Actual integral lifts express the same congruence as divisibility by $(p : \mathbb{Z}_p)^r$. Lean's rational valuation of zero is not itself an infinite-valued function. Exact valuation endpoints therefore include a separate nonzero conclusion or require a nonzero hypothesis. That distinction is essential when translating a lower bound into a typed target.

1.2 Current claim map

Topic in the main text	Retained Lean coverage	Present status
Nishibuchi Conjecture 3.9, all permitted primes and addresses	`NishibuchiCompletion.conjecture_3_9`, with the original integrality and degree-shift bridges	Compiled in the recorded source.

Topic in the main text	Retained Lean coverage	Present status
Four-packet all-row Kummer divisibility	`DyadicFourAllRows.normalized_precision`	Compiled, including row zero and every difference order.
Four-packet common-step precision, including the address factorial	`DyadicFourFinalStrengthening.normalized_step_precision` and `unnormalized_step_precision`	Compiled with exponent $k(1+v_2H)$, with $v_2(j!)$ for the original numbers.
Four-packet sharp first differences, least periods, and isometry	`DyadicFourLeastPeriods` and `DyadicFourIsometry`	Compiled under the stated address and positive-step hypotheses.
All prime-power moduli and all mixed steps	No matched general endpoint	Proved in the new continuation. Not formalized in Lean here.
Four-packet factorial gain and address surpluses	No matched higher-order endpoint	Proved in the new continuation. Not formalized in Lean here.
Exact higher differences at addresses zero and one and the mixed leading-digit criterion	No matched endpoint	Proved in the new continuation. Not formalized in Lean here.
Address-two stronger growth and exact power-of-two orders	No matched endpoint	Proved in the new continuation. Not formalized in Lean here.
Small-rank metric results beyond $N = 4$ and the all-rank lower-half metric theorem	No matched endpoint	Proved in the new continuation. Not formalized in Lean here.
Exact Euler Taylor radii at addresses zero, one, and two	No matched endpoint	Proved in the new continuation. Not implied by the retained polynomial regularity modules.
General exact higher-order law at addresses two and three and the unrestricted upper-half metric law	No completed endpoint	The stated unrestricted laws remain open or are refuted in the main text.

The table identifies mathematical topics and their formal coverage. The crosswalk links the corresponding monograph statements and source interfaces. Separate routes identify the strengthening statements and eight exact worked examples.

1.3 What the Nishibuchi capstone actually proves

Let p be prime, let $m > 0$ satisfy $m \mid p-1$ or $m = 2$, put $q = \operatorname{lcm}(2, p-1)$, and let $0 \le j < mp$. The capstone proves p-integrality of every original packet coefficient and, for every $r \ge 1$, the degree-indexed congruence

$$E^{(mp,j)}_{mpn+qp^r} \equiv E^{(mp,j)}_{mpn} \pmod{p^r} \qquad (n \ge r).$$

Its existential formulation supplies the positive threshold $n_0 = r$, so it also supplies $n_0 \le r$. It does not assert the smallest possible threshold. The source has no premise asking the caller to assume source flatness, a weighted certificate, or the desired congruence.

The divisor branch supplies the stronger sufficient row condition $r \le mn$. The arithmetic parameter reduction isolates the exceptional case $p = 2$, $m = 2$. At $p = 2$, $q = 2$. Replacing q by $p - 1 = 1$ would change the conjecture. The degree-shift theorem proves that the packet step

$$p^{r-1}\frac{q}{m}$$

produces exactly the Euler-degree increment qp^r.

The completion source contains 79 proof modules and 1,000 named axiom reports. The complete declaration index has 1,876 rows under 199 canonical files, including overlapping arithmetic and lifting developments. These are source counts and must not be added or treated as counts of mathematical discoveries.

The completion records include successful compilation, axiom checks and rejection tests. The capstone uses only propext, Classical.choice and Quot.sound. Static source and log checks do not rerun the Lean kernel.

1.4 The four-packet theorem already passed the row threshold

The earlier completion extracted a bound with exponent $\min(k, n)$. The retained strengthening subsequently replaced that cap by k using the unshifted operator

$$B = \frac{D^4 - 1}{2}.$$

Its charged reciprocal theorem proves that the source's flatness survives inversion, with the charge shift made explicit. The module `DyadicFourAllRows` then extracts the difference directly at degree $4n$. It has no $k \le n$ assumption and no artificial extraction at a negative degree.

The endpoint `DyadicFourFinalStrengthening.normalized_step_precision` states

$$v_2(\Delta_H^k C_{4,j}(n)) \ge k(1 + v_2 H) \qquad (j < 4,\ n, k \in \mathbb{N},\ H \ge 1),$$

with its zero-safe precision interpretation. The original-number endpoint adds $v_2(j!)$. For positive H, this is exactly the four-packet homogeneous specialization of the general mixed-step estimate in the new chapter. The source also includes zero step using its finite natural valuation `padicValNat 2 0 = 0`: every positive-order zero-step difference vanishes. At order zero, the statement is just the appropriate integrality assertion. Thus the source never forms the undefined paper expression $0 \cdot v_2(0)$.

For these four packets, the conjectured dyadic period already starts at row zero in the retained Lean source. The literal degree endpoint is `all_rows_period_degree`. The exact-period development goes further and proves

$$v_2(E^{(4,j)}_{4(n+H)} - E^{(4,j)}_{4n}) = v_2 H + B_j, \qquad (B_0, B_1, B_2, B_3) = (1, 1, 5, 3),$$

for positive H. It follows that the least positive row period modulo 2^r is

$$2^{\max(0, r - B_j)}.$$

The normalized bonuses are $(1, 1, 4, 2)$. The isometry endpoint uses a translated and rescaled packet, not the raw original sequence. Undoing its normalization gives the original image ball $j! + 2^{B_j}\mathbb{Z}_2$.

The written results extend the modulus range and operator patterns, strengthen higher differences by factorial and address gains, and give exact higher-order and analytic consequences. The already formalized four-packet statements retain their own coverage.

1.5 The strongest homogeneous congruence to formalize next

For $j \in \{0, 1, 2, 3\}$, $n \geq 0$, and $k, H \geq 1$, the final congruence in the main text is

$$\sum_{i=0}^{k} (-1)^{k-i} \binom{k}{i} E^{(4,j)}_{4(n+iH)} \equiv 0 \pmod{2^{\,v_2(k!)+kv_2H+A_j(k)}},$$

where

$$A_0(k) = A_1(k) = k, \qquad A_2(k) = \max\{k+4,\ 2k + \lfloor k/2 \rfloor + 1\}, \qquad A_3(k) = k + 2.$$

This displayed exponent includes the address factorial. Using it directly for the normalized $C_{4,j}$ would introduce an extra digit at addresses two and three. The lower bound holds at every base row, including zero. Equality holds for every positive order and positive homogeneous step at addresses zero and one. At address two, the exact laws proved in the chapter cover orders that are powers of two, including one and two, with the explicit small-order exceptions stated there. This is not a theorem asserting equality at every address-two order.

A direct formal target should use `Mahler.difference H k (Congruential.unnormalized 4 j) n`, the natural exponent `padicValNat 2 k.factorial + k * padicValNat 2 H + A j k`, and `GlobalEulerBoundary.precision`. Its hypotheses are $j < 4$, $0 < k$, and $0 < H$. That target reuses the original definitions and preserves the chapter's quantifiers. It should not replace the rational sequence by a separately named experimental recurrence without a coefficient-identity bridge.

The proof of the new factorial term is a divided-power argument. At addresses zero and one, its external arithmetic input is the exact classical Frobenius congruence for ordinary Euler numbers, in the form checked in the main text's source record. The Bernoulli central-factorial argument at address two proves its divided-power integrality internally. A Lean completion will need the exact ordinary-Euler input formalized or imported as a proved theorem with a matched statement. A custom axiom standing in for that input would change the formal coverage and must not be hidden under an unchanged completion label.

1.6 General prime-power closure: a reusable target

For $N = p^a$, $a \geq 1$, and $j < N$, put $C(n) = C_{N,j}(n)$. The general theorem is most naturally phrased for the sign-adjusted sequence

$$A(n) = (-1)^n C(n).$$

For positive steps $H_1, \ldots, H_k$, it proves

$$v_p(\Delta_{H_1} \cdots \Delta_{H_k} A(n)) \geq k + \sum_{i=1}^{k} v_p H_i.$$

For the raw sequence, define $T_H f(n) = f(n+H) - (-1)^H f(n)$. The equivalent original-number statement is

$$v_p(T_{H_1} \cdots T_{H_k} E^{(N,j)}(n)) \geq v_p(j!) + k + \sum_{i=1}^{k} v_p H_i, \qquad E^{(N,j)}(n) = E_{Nn}^{(N,j)}.$$

At $p = 2$, the sign adjustment and an integral charge shift give the ordinary mixed-difference theorem for $C_{N,j}$ itself. The degenerate dyadic modulus $N = 1$ has $C(n) = (-1)^n$ and is handled directly. At an odd prime, ordinary unsigned differences of the raw sequence need not satisfy the same estimate: $C_{N,0}(0) = 1$ and $C_{N,0}(1) = -1$, so the first unit-step difference is -2.

A useful formalization order is:

1. Prove integral Hurwitz coordinates are closed under products, derivatives, and inversion of a unit constant coefficient. Retained `HurwitzConvolution`, `HurwitzInverse`, and `DworkAlgebra` provide reusable constructions. Their exact coefficient domains must be matched before reuse.
2. Prove interior binomial divisibility $p \mid \binom{p^a}{r}$ for $0 < r < p^a$, and record the integral coefficients in the charged operator product formula.
3. Generalize the charged reciprocal closure from D^4 to D^N, keeping the source and inverse charges visible. The critical induction isolates the unique term containing the highest inverse order. No hypothesis $k \leq n$ is permitted.
4. Prove flatness of the actual source $g_{N,j}(n) = \prod_{i=1}^{j}(1 + (N/i)n)^{-1}$. Every slope N/i belongs to $p\mathbb{Z}_p$ because $1 \leq i < N = p^a$. Prove the reciprocal affine-factor finite-difference identity before taking products.
5. Decode the reciprocal coefficient at a nonnegative packed degree, then transfer to rational precision and to the original factorial normalization.
6. Prove mixed-step amplification, with independent step valuations added, and specialize to homogeneous steps only after the general target is established.

This sequence isolates the new universal arithmetic infrastructure. The retained $N = 4$ charged closure proves a special case, but its source signature does not quantify over every prime-power modulus. A future generalized file should remain a new endpoint until its statement and axiom closure have been checked.

1.7 Divided powers, factorial gains, and equality

For four-packet normalized coefficients, the factorial theorem states

$$v_2(\Delta_{H_1} \cdots \Delta_{H_k} C_{4,j}(n)) \geq k + v_2(k!) + \sum_{i=1}^{k} v_2 H_i + \beta_j, \qquad (\beta_0, \beta_1, \beta_2, \beta_3) = (0, 0, 3, 1),$$

for $k \geq 1$. Multiplication by $j!$ changes the address surpluses to $(0, 0, 4, 2)$ for the original numbers. At address two, the additional bound

$$v_2(\Delta_{H_1} \cdots \Delta_{H_k} C_{4,2}(n)) \geq 2k + v_2(k!) + \lfloor k/2 \rfloor + \sum_{i=1}^{k} v_2 H_i$$

combines with the first bound by taking their maximum.

The formal proof must distinguish a valuation lower bound from the evaluation of its leading unit. Divided-power integrality proves the lower bound. Exactness additionally requires a parity calculation

after dividing by the claimed power of two. That calculation is where unequal steps can cancel. At addresses zero and one, let

$$V = k + v_2(k!) + \sum_{i=1}^{k} v_2 H_i.$$

The new chapter proves exact valuation V if k is odd or the number of even steps is even. If k is even and the number of even steps is odd, the leading digit cancels and the valuation is at least $V + 1$. That last case does not carry a uniform formula for the deeper valuation.

For a homogeneous step, the number of even steps is either zero or k. The criterion therefore always gives exactness at addresses zero and one. This explains why a true homogeneous equality can fail when a single step is changed. For example,

$$\Delta_1\Delta_2 C_{4,0}(0) = -33728,$$

has valuation 6, whereas the mixed baseline is 4. The same pattern at address one has value $-150208/585$ and valuation 6. These examples should become exact rational negative controls for a proposed unconditional mixed equality. They should not be used as a substitute for the general parity proof.

At address two, the exact mixed-step exponent is $4 + \sum v_2 H_i$ at order one, $6 + \sum v_2 H_i$ at order two, and

$$2k + v_2(k!) + k/2 + \sum v_2 H_i$$

at powers of two $k \geq 4$. The split between these three targets is deliberate. A theorem with the final expression at order one would not state the correct sharp exponent. General exact higher-order laws at addresses two and three remain outside the completed formal and mathematical register.

The proof route uses two Gaussian-scaled Euler or Bernoulli umbrae over $\mathbb{Q}_2(i)$ and a descent back to rational coefficients. Lean obligations include the base change, the Gaussian scalar identities, the divided-power product and composition laws, and the rational descent. Treating the symbolic complex expression as though it were already a rational integral element would omit a substantive bridge. The unbounded exactness subsequence at address two also needs its parity proof. A computed prefix through order 512 does not supply that bridge.

1.8 Analytic consequences require their own bridge

The factorial Newton estimates are converted into Taylor coefficients using the Stirling change of basis, with convergence and uniformity justified. They imply an exact Taylor radius 2 at every integral center for addresses zero and one. The address-two bounds, together with the sharp power-of-two coefficient subsequence, give exact radius $2^{5/2}$. The address-three result gives a radius of at least 2. Its exact radius is not claimed.

A formal endpoint should specify the coefficient field, the absolute value normalization $|2|_2 = 1/2$, the chosen center, and the meaning of radius. If the radius is viewed through an extension containing points outside $\mathbb{Q}_2$, the relevant convergence statement needs that ambient extension specified. The root-test coefficient rate itself can be stated independently. A generic Kummer bound alone does not establish these analytic radii. The retained `PolynomialAnalyticEvaluation`, `PolynomialAnalyticBlocks`, and local implicit-graph modules concern different objects and do not close this argument.

A future Lean proof should separately verify Newton interpolation equals the original rational packet on natural inputs, the Newton-to-Taylor coefficient identity, the coefficient lower bounds, the

exact subsequence supplying the upper radius bound, and convergence on the asserted disk. No result about finitely many numerical coefficients can be promoted to the exact radius without that unbounded subsequence argument.

1.10 A clean completion criterion for the new formal layer

A theorem is formally checked only after its exact statement and source are fixed, its dependencies are identified, positive examples compile, relevant false strengthenings fail for the expected reason, and its axiom closure is recorded. The controls cover odd-prime raw differences, unconditional mixed equality, zero steps, the address factorial, and the higher-rank upper-half metric boundary.

Proof sources must not replace an argument with a placeholder, an axiom for the desired conclusion, or precomputed coefficients. Imported arithmetic needs a matched theorem and a justified bridge to the chapter's convention. Common-step and mixed-step bounds, and finite tests and universal statements, remain distinct. The inherited capstone does not automatically certify the stronger written results.

2 How to read the formal development

The development uses two complementary mathematical languages. Arithmetic packets begin with sequences and formal power series, then transport divisibility through exact coordinate changes. Polynomial lifting begins with a finite residual equation, passes to compatible digit towers, and finally enters complete p-adic and analytic spaces. The transition between these languages is explicit: a rational coefficient has to be shown integral before it becomes a p-adic integer. An integer congruence tower has to be shown Cauchy before it becomes a root. A formal polynomial derivative has to be identified with a strict Fréchet derivative before it supports an analytic inverse theorem.

This guide follows those transitions. Read the *contract* before the excerpt: it states the coefficient domain, ambient dimensions, and hypotheses that may be declared earlier in the source. The excerpt is an exact contiguous selection from a preserved Lean file. Its line range and source hash are supplied in the accompanying excerpt inventory. The proof reading then explains what the displayed tactics accomplish mathematically. A theorem imported from another module is a dependency, not a hidden new assumption. A hypothesis supplied to a theorem remains a mathematical assumption even when its name does not appear in the theorem's axiom closure.

2.1 Statements, constructions, audits, and identifiers

The retained preceding consolidated manuscript links 62 statements to 202 named source declarations. That index resolves names and source identities. It does not prove that every informal sentence equals a Lean statement. Several declarations may establish one displayed theorem, while one source theorem may support several expository consequences. The restored Bernoulli specialization has a classical formal-series derivation in the manuscript, but no dedicated Lean bridge was matched. The manuscript's open problems retain their open status.

The full declaration index has 1,876 rows. A row records a declaration kind, qualified name, and entire source-file hash. Byte-identical copies are collapsed. Distinct source files remain separate. There are 1,863 distinct kind/name pairs, including 1,542 distinct names whose command kind is theorem. These are identifier counts, not counts of independent mathematical results. The rows also contain constructions, statement contracts, examples and control support. Thirteen names have more than one source file.

The polynomial regularity development contains 322 theorem commands, 76 definitions and seven abbreviations in 55 proof modules. Eight support modules and thirteen contract modules bring the named audit to 515 declarations. Its 415 theorem commands include 61 support and 32 contract commands.

2.2 Reading the Lean notation

`Fin d → R` means a vector with exactly d coordinates over R. In rectangular lifting, d counts unknowns and e counts equations. In a parameter split, `Fin (e+k) → R` separates e solved coordinates and k free parameters. A theorem using `Fin (m+k)` may instead have m solved coordinates and e equations. The distinction matters when a fiber has p^{m-e} elements.

`A →ₗ[R] B` is a linear map, while `A →L[R] B` is a continuous linear map. An arrow decorated `≃L[R]` is a continuous linear equivalence. The analytic derivative is a continuous linear map. A raw matrix

becomes one through the explicitly defined `matrixCLM`. `IsUnit J` for a square matrix means it is invertible in the matrix ring. It does not mean each matrix entry is a scalar unit.

`ZMod p` is the residue ring. The source uses `Fact p.Prime` when it needs a finite field, rank, or p-adic objects. Some affine and integer polynomial statements require only $p > 0$ or $q > 0$. Their quotient algebra does not require primality. A hypothesis `1 ≤ L` supplies the depth needed for polynomial first-order linearization. The affine depth-zero case is valid because an affine map has no quadratic Taylor remainder.

`∃! b, P b` means there is exactly one object satisfying the full predicate P. A local root theorem's predicate includes its residue ball. It does not imply that the polynomial has only one root in the entire field. Likewise, an analytic graph theorem supplies open parameter and solved-coordinate neighborhoods. Global uniqueness is outside its conclusion.

3 Exact coordinates before arithmetic estimates

3.1 Residue projectors are coefficient filters

Contract. For an additive commutative monoid R, a positive modulus N, and a sequence $a : \mathbb{N} \to R$, the residue packets sum to a. The coefficient-level idempotent and orthogonality laws need only a zero element.

Lines 38–46; `KomorebiPaperIX.ResiduePackets.packet_reconstruction`.

```
theorem packet_reconstruction [AddCommMonoid R] {N : ℕ} (hN : 0 < N) (a : ℕ → R) :
    ∑ j ∈ Finset.range N, packet N j a = a := by
  funext n
  simp only [Finset.sum_apply, packet]
  rw [Finset.sum_eq_single (n % N)]
  · simp
  · intro b _ hb
    simp [Ne.symm hb]
  · simp [Nat.mod_lt n hN]
```

Proof reading. Function extensionality reduces the sequence identity to one coefficient n. The only nonzero summand is indexed by n mod N. `Finset.sum_eq_single` separates that summand from the rest. `Nat.mod_lt n hN` proves its address lies inside the chosen finite range. Positivity justifies the finite address set. There is no division by N and no root-of-unity hypothesis.

A residue projector is a selector on the degree address. Applying it twice keeps the same coefficients. Projectors with distinct addresses cannot both retain the same degree. Refinement to a multiple modulus groups fine addresses according to their coarse remainder. These are exact identities before reduction modulo a prime. The power-series versions use coefficient extensionality, so the same proof mechanism acts on `PowerSeries R`.

3.2 Triangular reconstruction constructs the solution

The source does not assume that an infinite triangular system already has a solution. It defines forward substitution recursively, using only indices $k < n$ at row n. The `termination_by n` declaration verifies the recursion decreases. Over a field the formula is defined even when a diagonal vanishes, but the row equation and uniqueness theorem explicitly require nonzero diagonal entries.

Contract. F is a field, T is an infinite coefficient array, every T_{nn} is nonzero, and a satisfies every finite row equation. Then a equals the recursively constructed solution.

Lines 35–49; `KomorebiPaperIX.Triangular.solve_unique`.

```
theorem solve_unique (T : ℕ → ℕ → F) (b a : ℕ → F)
    (hT : ∀ n, T n n ≠ 0)
    (ha : ∀ n, (∑ k : Fin n, T n k * a k) + T n n * a n = b n) :
```

```
    a = solve T b := by
  funext n
  induction n using Nat.strong_induction_on with
  | h n ih =>
    have hs : (∑ k : Fin n, T n k * a k) = ∑ k : Fin n, T n k * solve T b k := by
      apply Finset.sum_congr rfl
      intro k _
      rw [ih k k.isLt]
    have hr := ha n
    rw [hs] at hr
    have he := solve_row T b hT n
    exact (mul_left_cancel₀ (hT n)) (add_left_cancel (hr.trans he.symm))
```

Proof reading. Strong induction first replaces each earlier unknown a_k by the recursive value. The two row equations then have identical earlier sums. Cancelling the sum leaves equality after multiplication by T_{nn}. Nonzero diagonal cancellation gives equality of the current entries. Function extensionality assembles all rows. The argument needs no convergence or boundedness of an infinite matrix. Each row is a finite calculation.

Contract. For integer coefficients and integer right-hand side, the product $D_n = \prod_{r=0}^{n} T_{rr}$ clears the rational solution's denominator at row n. Every diagonal remains nonzero.

Lines 106–127; `KomorebiPaperIX.Triangular.solve_denominator_integral`.

```
theorem solve_denominator_integral (T : ℕ → ℕ → ℤ) (b : ℕ → ℤ)
    (hT : ∀ n, T n n ≠ 0) (n : ℕ) :
    Integral ((denominator T n : ℚ) * solve (fun i j => (T i j : ℚ)) (fun i => (b i : ℚ)) n) := by
  induction n using Nat.strong_induction_on with
  | h n ih =>
    cases n with
    | zero =>
      simp only [denominator_zero, solve_zero]
      have h0 : (T 0 0 : ℚ) ≠ 0 := Int.cast_ne_zero.mpr (hT 0)
      rw [mul_div_cancel₀ _ h0]
      exact integral_int _
    | succ n =>
      rw [solve_step, denominator_succ, Int.cast_mul]
      have hn : (T (n + 1) (n + 1) : ℚ) ≠ 0 := Int.cast_ne_zero.mpr (hT (n + 1))
      rw [mul_assoc, mul_div_cancel₀ _ hn]
      rw [mul_sub, Finset.mul_sum]
      apply integral_sub (integral_mul (integral_int _) (integral_int _))
      apply integral_sum
      intro k _
      rw [mul_left_comm]
      exact integral_mul (integral_int _)
        (integral_promote (denominator_dvd T (Nat.le_of_lt_succ k.isLt)) (ih k k.isLt))
```

Proof reading. The induction separates row zero from a successor row. At a successor, $D_{n+1} = D_n T_{n+1,n+1}$ cancels the new denominator. Earlier denominators divide D_n, allowing `integral_promote`

to place every earlier term under one common integer multiplier. The proof establishes an integral multiple of the actual recursive solution. It does not assert that the product is the smallest denominator. Negative diagonal entries are allowed, since only nonvanishing and divisibility are used.

3.3 EGF multiplication is Hurwitz convolution

Contract. Over a characteristic-zero field in the source coordinates, encoding divides the nth sequence entry by $n!$, and decoding multiplies the power-series coefficient by $n!$. The two operations are inverse.

Lines 52–60; `KomorebiPaperIX.EGF.egf_product`.

```
theorem egf_product (h a : ℕ → K) (n : ℕ) :
    decode (encode h * encode a) n =
      ∑ r ∈ Finset.range (n+1), (n.choose r : K) * h r * a (n-r) := by
  simp only [decode, coeff_mul, Finset.Nat.sum_antidiagonal_eq_sum_range_succ_mk,
    encode_coeff, Finset.sum_mul]
  apply Finset.sum_congr rfl
  intro r hr
  rw [Nat.cast_choose K (Finset.mem_range_succ_iff.mp hr)]
  ring
```

The binomial coefficient in the displayed convolution records the factorial change of coordinates. Ordinary power-series multiplication uses an unweighted coefficient convolution. The exponential coordinate multiplication uses $\binom{n}{k}$. A raw formal coefficient must therefore be distinguished from its degree-indexed generalized Euler number. Replacing one by the other without restoring the factorial changes p-adic precision.

Proof reading. The proof unfolds the product coefficient over finitely many pairs with sum n, substitutes the encoded entries, and proves the factorial identity behind the binomial coefficient. Nonzero factorial casts justify field cancellation. The resulting law transports exact inverse identities and reconstruction statements into sequence coordinates. The formal series need not converge analytically.

3.4 Finite differences and the Mahler basis

Contract. R is a commutative ring. The finite Mahler identity reconstructs any sequence value $f(n)$ from its first $n+1$ forward-difference coefficients. All sums are finite.

Lines 55–57; `KomorebiPaperIX.Mahler.finite_mahler_reconstruction`.

```
theorem finite_mahler_reconstruction (f : ℕ → R) (n : ℕ) :
    f n = ∑ r ∈ Finset.range (n+1), coefficient f r * (n.choose r : R) := by
  simpa [coefficient, difference, nsmul_eq_mul, mul_comm] using shift_eq_sum_fwdDiff_iter 1 f n 0
```

The change of basis is

$$f(n) = \sum_{k=0}^{n} \binom{n}{k} \Delta^k f(0).$$

The inverse relation expresses $\Delta^k f(0)$ as a signed binomial sum of the first $k+1$ values. No infinite Mahler-series convergence theorem is required for this finite identity. Later p-adic bounds put valuations on these exact coefficients and turn a finite coordinate theorem into precision estimates.

A weight condition on the kth coefficient controls higher differences by divisibility. The weighted difference modules formulate that condition explicitly and prove the translation by finite sums. A theorem about all orders therefore depends on the weight hypothesis for all the relevant coefficients. It cannot be inferred from a small computed prefix.

3.5 Finite units and Chinese remainders

Contract. For a prime p and $L \in \mathbb{N}$, the finite-unit module decomposes a unit modulo p^{L+1} into the source's torsion and principal components. Its uniqueness proof uses the uniquely lifted torsion representative and cancellation.

Lines 134–144; `KomorebiPaperIX.FiniteUnits.decomposition_unique`.

```
theorem decomposition_unique (L : ℕ) (a w v : (ZMod (p^(L+1)))ˣ)
    (ha : w*v=a) (hw : w^(p-1)=1) (hv : residueUnits p L v=1) :
    w=omega p L a ∧ v=principal p L a := by
  have hr : residueUnits p L w=residueUnits p L a := by
    rw [← ha, map_mul, hv, mul_one]
  have he := omega_unique p L a w hw hr
  refine ⟨he, ?_⟩
  subst w
  apply mul_left_cancel (a := omega p L a)
  rw [ha]
  exact (finite_unit_decomposition p L a).1.symm
```

The displayed source theorem applies to prime p, including $p = 2$. It compares the reduced residue of w with that of a, invokes the uniquely lifted torsion representative, and then cancels that factor to identify the principal component. For odd primes the familiar coprime torsion/principal orders explain this structure, but the Lean endpoint uses its proved lifted-root uniqueness. The dyadic development additionally supplies the finer sign/principal decomposition in its separate module.

Contract. The displayed CRT equivalence identifies addresses modulo $2^a M$ with addresses modulo 2^a and M, where M is odd. Oddness proves the coprimality needed by the ring equivalence.

Lines 13–17; `KomorebiPaperIX.CRTPackets.addressEquiv`.

```
def addressEquiv (a M : ℕ) (hM : Odd M) :
    ZMod (2^a*M) ≃+* ZMod (2^a) × ZMod M :=
  ZMod.chineseRemainder (by
    apply Nat.Coprime.pow_left
    exact (Nat.coprime_two_left).mpr hM)
```

Proof reading. The equivalence carries both directions and their inverse laws. Packet factorization then compares the retained degree address through that equivalence. The algebra concerns residue addresses and coefficients, not an analytic tensor-product completion. This is why the finite arithmetic layer can be reused without adding convergence claims.

4 From packet coefficients to Nishibuchi's conjecture

4.1 Rational precision includes zero

Contract. Fix a prime p. For a rational number x and an integer L, `precision p L x` means $x = 0$ or $v_p(x) \geq L$.

Lines 18–18; `KomorebiPaperIX.GlobalEulerBoundary.precision`.

```
def precision (L : ℤ) (x : ℚ) : Prop := x=0 ∨ L≤padicValRat p x
```

The explicit zero alternative avoids relying on a finite-valued implementation of the valuation at zero. It also allows negative precision exponents: dividing an integral p-adic quantity by an integer normalization can reduce the bound below zero. The source's `precision` predicate is not divisibility inside $\mathbb{Q}$, where every nonzero scalar is a unit. Divisibility statements live in $\mathbb{Z}$, $\mathbb{Z}_p$, or a stated coefficient ring, and a separate bridge transports them to rational valuations.

Let $N = mp$ with $m > 0$, $m \mid p-1$, and $0 \leq j < N$. The unnormalized sequence is lifted to $\mathbb{Z}_p$ only after integrality is proved. Its higher differences use a packet step that is a multiple of $(p-1)/m$. The arithmetic core supplies a bound of the form

$$p^{\min(k,mn)} \mid \Delta^k_{u(p-1)/m} A_{N,j}(n).$$

Contract. The prime hypothesis, divisor condition $m \mid p-1$, positive m, and address bound $j < mp$ are all required. The sequence in the theorem is the actual integral lift of the unnormalized generating-series coefficients.

Lines 79–85; `KomorebiPaperIX.AllResidueEuler.global_unnormalized_bound`.

```
theorem global_unnormalized_bound (m j u k n : ℕ)
    (hm : m|p-1) (hmpos : 0<m) (hj : j<m*p) :
    (p:ℤ_[p])^(min k (m*n)) |
      difference (u*((p-1)/m)) k (unnormalizedLift p m j hm hmpos hj) n := by
  exact packet_divisibility p m hm hmpos
    (unnormalizedSeries (m*p) (Nat.mul_pos hmpos (Fact.out : p.Prime).pos).ne' j)
    (all_residue_flat p m hm hmpos j hj) (unnormalized_support (m*p) _ j) u k n
```

Proof reading. The theorem invokes `packet_divisibility` with three distinct inputs: the actual unnormalized series, its all-residue flatness theorem, and its support theorem. The interface does not permit an arbitrary series to acquire this bound. The difficult recurrence/flatness propagation resides in its imported arithmetic modules, whose explicit declarations remain in the complete catalog. The short endpoint proof is a composition of those established inputs, not an independent numerical experiment.

The normalization transfer must retain its factorial loss. A bound on $A_{N,j}$ gives a bound on the normalized coefficient only after subtracting the valuation of the normalization factor. The retained normalization counterexample shows why a universal loss-free transfer is false. A theorem with a stronger hypothesis in a standard window must not be silently extended to every row without that transfer.

4.2 A Newton expansion converts differences into a period

Contract. R is a commutative ring, p is prime, $r > 0$, and every order-k difference at the chosen base point is divisible by $p^{\min(k,r)}$. The conclusion is one period displacement at that base point.

Lines 46–67; `KomorebiPaperIX.PeriodFromDifferences.prime_power_period`.

```
theorem prime_power_period (f : ℕ → R) (h n r : ℕ) (hr : 0<r)
    (H : ∀ k, (p:R)^(min k r) | difference h k f n) :
    (p:R)^r | f (n+p^(r-1)*h)-f n := by
  rw [displacement_expansion]
  apply Finset.dvd_sum
  intro k hk
  have hkr : k+1 ≤ p^(r-1) := by have := Finset.mem_range.mp hk; omega
  by_cases hsmall : k+1 < r
  · have hd := H (k+1)
    rw [min_eq_left (by omega : k+1≤r)] at hd
    obtain ⟨a,ha⟩ := hd
    rw [ha, ←mul_assoc]
    have hb := binomial_precision p (r-1) (k+1) (by omega) hkr
    rw [Nat.sub_add_cancel (by omega : 1≤r)] at hb
    have hcast : (p:R)^r | (((p^(r-1)).choose (k+1):ℕ):R)*(p:R)^(k+1) := by
      obtain ⟨b,hb⟩ := hb
      refine ⟨(b:R), ?_⟩
      simpa only [Nat.cast_mul, Nat.cast_pow] using congrArg (fun a:ℕ => (a:R)) hb
    exact dvd_mul_of_dvd_left hcast a
  · have hd := H (k+1)
    rw [min_eq_right (by omega : r≤k+1)] at hd
    exact dvd_mul_of_dvd_right hd _
```

Proof reading. The displacement expansion writes the change at p^{r-1} steps as a finite sum of binomial coefficients times higher differences. For an order $k < r$, the difference contributes p^k and the binomial coefficient contributes the missing digits. For $k \geq r$, the difference itself supplies the whole p^r. The proof explicitly splits these cases. It does not require division in R. Integer divisibility of binomial coefficients is cast into the ring.

When the packet bound supplies $\min(k, mn)$, a sufficient threshold $r \leq mn$ gives the hypothesis above. The endpoint uses the simpler threshold $n \geq r$ valid across the allowed parameter families. This is a sufficient starting index. The proof makes no assertion that the threshold is the smallest possible one.

4.3 Packet address and degree address are different indices

The generalized Euler sequence is degree-indexed, while a residue packet sequence is indexed by its packet row n. The source proves its reciprocal generating identity before presenting the external conjecture: the unnormalized series multiplied by the original exponential section is X^j. Thus the degree sequence is connected to the defining source series, not just assigned a suggestive name.

Set $q = \operatorname{lcm}(2, p-1)$. The allowed divisor branch has packet shift $p^{r-1}(q/m)$, which becomes degree shift qp^r after multiplication by mp. The exceptional allowed family is $p = 2, m = 2$. For odd primes, the option $m = 2$ already belongs to the divisor branch because $2 \mid p-1$.

Contract. The integral quotient q/m is justified by $m \mid p-1$ or $m = 2$. The degree identity also requires $r > 0$ so that $p^r = p^{r-1}p$.

Lines 89–96; `KomorebiPaperIX.NishibuchiCompletion.original_degree_shift`.

```
theorem original_degree_shift (m n r:ℕ) (h:m|p-1 ∨ m=2) (hr:0<r) :
    m*p*(n+p^(r-1)*(displacementFactor p/m)) =
      m*p*n+displacementFactor p*p^r := by
  have hq := Nat.mul_div_cancel' (modulus_divides_displacement p m h)
  have hp : p^r=p^(r-1)*p := by rw [←pow_succ,Nat.sub_add_cancel (by omega : 1≤r)]
  calc
    _ = m*p*n+(m*(displacementFactor p/m))*(p^(r-1)*p) := by ring
    _ = _ := by rw [hq,hp]
```

Proof reading. The proof establishes $m(q/m) = q$ and rewrites the exponent successor using $r \geq 1$. The remaining identity is ring arithmetic. Natural-number division is not an approximate operation here: its exact cancellation is justified by divisibility. Forgetting that hypothesis would change the intended displacement.

4.4 The completion theorem exposes its full range

Contract. p is prime, $m > 0$, $j < mp$, and $m \mid p-1$ or $m = 2$. Every degree-mpn coefficient is p-integral. For each $r > 0$, a positive starting index $n_0 \leq r$ exists, and all $n \geq n_0$ satisfy the stated degree displacement congruence.

Lines 128–141; `KomorebiPaperIX.NishibuchiCompletion.conjecture_3_9`.

```
theorem conjecture_3_9 (m j:ℕ) (hmpos:0<m) (hj:j<m*p) (h:m|p-1 ∨ m=2) :
    (∀n, ((generalizedEuler (m*p) (Nat.mul_ne_zero hmpos.ne' (Fact.out:p.Prime).ne_zero)
      j (m*p*n):ℚ):ℚ_[p]) ∈ PadicInt.subring p) ∧
    ∀r:ℕ, 0<r → ∃n0:ℕ, 0<n0 ∧ n0≤r ∧ ∀n:ℕ, n0≤n →
      precision p (r:ℤ)
        (generalizedEuler (m*p) (Nat.mul_ne_zero hmpos.ne' (Fact.out:p.Prime).ne_zero) j
          (m*p*n+displacementFactor p*p^r)-
         generalizedEuler (m*p) (Nat.mul_ne_zero hmpos.ne' (Fact.out:p.Prime).ne_zero) j (m*p*n))
          ↪  := by
  constructor
  · intro n
    rw [generalizedEuler_at_packet]
    exact full_integrality p m j n hmpos hj h
  · intro r hr
    exact ⟨r,hr,le_rfl,fun n hn => full_period_degree p m j r n hmpos hj h hr hn⟩
```

Proof reading. The conjunction separates integrality from eventual periodicity. Integrality first rewrites the degree coefficient at mpn into the packet coefficient, then invokes the proved integral lift. The period witness is exactly $n_0 = r$. The degree-period theorem is supplied for every later n, so the existential threshold is constructive at the statement level even though the ambient development uses classical mathematics.

This endpoint proves the original range recorded in the retained external comparison. The prime, parameter, address, and displacement conventions all remain visible. It supplies an eventual period and integrality, while the later dyadic modules prove sharper exact periods in their own specified family. It does not extend the conjecture to arbitrary m, identify an optimal starting index, or establish a least period in every prime family.

5 Reconstruction, sharp dyadic displacement, and isometry

5.1 Odd reconstruction separates identity from precision

Contract. The odd Euler reconstruction is an exact identity over $\mathbb{Z}$ for every odd length p, even when that length is composite. The prime-only corollary is a specialization.

Lines 80–87; `KomorebiPaperIX.OddEuler.odd_euler_reconstruction`.

```
theorem odd_euler_reconstruction (p n : ℕ) (hp : Odd p) :
    eulerEven n = ∑ m ∈ Finset.range (n+1),
      ((2*n).choose (2*m) : ℤ) * inverseEven m * (p:ℤ)^(2*m) * source p (2*(n-m)) := by
  have h := reconstruction_all_indices p (2*n) hp (even_two_mul n)
  rw [euler_even] at h
  rw [sum_even_terms (fun r => ((2*n).choose r : ℤ)*inverseCoeff r*(p:ℤ)^r*source p (2*n-r))
    (fun m => by rw [inverse_odd_zero _ (by exact ⟨m,rfl⟩)]; simp)] at h
  simpa only [inverseEven, Nat.mul_sub_left_distrib] using h
```

The series identity underlying this theorem multiplies a rescaled squared reciprocal series by the even part of the source series. It then extracts exponential coordinates, proves odd terms vanish, and changes from arbitrary indices to even indices. The coefficient $\binom{2n}{2m}$ and the factor p^{2m} come from that exact coordinate calculation. The source separately proves the signed zigzag identity for the inverse coefficient. The sign is not inferred from a plotted prefix.

Contract. Truncation includes $m = 0, \dots, \min(M, n)$. Every omitted summand has the stated even weight.

Lines 144–150; `KomorebiPaperIX.OddEuler.odd_euler_supercongruence`.

```
theorem odd_euler_supercongruence (p n M : ℕ) (hp : Odd p) :
    (p:ℤ)^(2*M+2) ∣ eulerEven n - truncation p n M := by
  rw [odd_euler_reconstruction p n hp]
  have h := Filtered.even_weight_tail (p:ℤ)
    (fun m => ((2*n).choose (2*m):ℤ)*inverseEven m*source p (2*(n-m))) n M
  rw [filter_range_le] at h
  simpa only [truncation, mul_assoc, mul_left_comm, mul_comm] using h
```

Proof reading. The full sum is split into retained and omitted indices. For an omitted m, $m \geq M+1$, so its factor p^{2m} contains p^{2M+2}. The tail theorem is therefore an integer divisibility statement. If $M \geq n$, there are no omitted terms and the truncation equals the full value exactly. No convergence question arises, because each row has only $n+1$ terms.

5.2 The dyadic transform has its own coefficients

Contract. The dyadic Euler reconstruction uses its specifically constructed dyadic source and integral transform coefficients. It is not obtained by substituting $p = 2$ into a theorem whose hypothesis is `Odd p`.

Lines 26–45; `KomorebiPaperIX.DyadicReconstruction.dyadic_reconstruction`.

```
theorem dyadic_reconstruction (n : ℕ) :
    (eulerEven n : ℚ) = ∑ m ∈ Finset.range (n+1), summand n m := by
  have hs := congrArg (fun f => EGF.decode f (2*n)) dyadic_reconstruction_series
  have hp := EGF.egf_product (EGF.decode (rescale (2:ℚ) inverseSeries))
    (EGF.decode DyadicSeries.sourceSeries) (2*n)
  simp only [EGF.encode_decode] at hp
  have he : EGF.decode OddPower.sech (2*n) = (eulerEven n : ℚ) := by
    rw [← euler_egf, EGF.decode_encode, euler_even]
  rw [hp,he] at hs
  rw [OddEuler.sum_even_terms _ (fun m => by
    simp [EGF.decode, coeff_rescale, inverse_odd_coefficient])] at hs
  rw [← hs]
  apply Finset.sum_congr rfl
  intro m hm
  simp only [EGF.decode, coeff_rescale, inverse_even_coefficient,
    ← Nat.mul_sub_left_distrib, source_even_coefficient]
  unfold summand
  rw [Nat.descFactorial_eq_factorial_mul_choose]
  push_cast
  field_simp
```

The dyadic coefficient analysis includes the valuation of the transform coefficients and of the source terms. Its sharper truncation bound is

$$2^{4M+3} \mid E_{2n} - T_M(n)$$

in the p-adic integral coordinates. That exponent comes from the omitted index bound and the valuation of the dyadic coefficient κ_m. The first omitted term is separately analyzed to show sharpness where the stated row/depth hypotheses apply.

Contract. The displayed uniform sharp tail bound holds for all natural n, M. Full-depth truncations have zero error. A nonzero exact valuation for the first omitted error has its own boundary hypotheses.

Source: `strengthening/formalization/DyadicSharpTower.lean`.

Lines 176–189; `KomorebiPaperIX.DyadicSharpTower.dyadic_supercongruence_sharp`.

```
theorem dyadic_supercongruence_sharp (n M : ℕ) :
    (2:ℤ_[2])^(4*M+3) | (EulerCoefficients.eulerEven n:ℤ_[2]) - truncationPadic n M := by
  rw [dyadic_reconstruction_padic, truncationPadic, ← OddEuler.filter_range_le]
  classical
  rw [← Finset.sum_filter_add_sum_filter_not (Finset.range (n+1)) (fun m => m ≤ M)
    (summandPadic n), add_sub_cancel_left]
  apply Finset.dvd_sum
  intro m hm
  obtain ⟨_, hm⟩ := Finset.mem_filter.mp hm
  have hpos : 0 < m := by omega
  have hpow : (2:ℤ_[2])^(4*M+3) | (2:ℤ_[2])^(4*m-1) := pow_dvd_pow 2 (by omega)
```

```
  rw [summandPadic_kappa]
  exact dvd_mul_of_dvd_left (dvd_mul_of_dvd_left
    (hpow.trans (kappaPadic_divisible m hpos)) _) _
```

Proof reading. The proof splits the finite reconstruction sum by the predicate $m \le M$. In the complement, $m > 0$, allowing the coefficient divisibility theorem. The exponent comparison $4M + 3 \le 4m - 1$ supplies the uniform bound. The calculation is a universal finite-sum proof. Checking numerical rows is independent bounded evidence about examples, not the reason this theorem holds.

5.3 Dominance gives an exact valuation

A lower bound on every difference does not itself determine a least period. The sharp modules isolate a nonzero leading Newton contribution whose valuation is smaller than all remaining contributions. In a nonarchimedean field, that strict separation forces the whole sum to have the leading term's valuation. A tie in the lowest valuations could allow cancellation, so the strict tail estimate is essential.

Contract. For each of the four normalized dyadic addresses $j < 4$ and each positive natural displacement T, the difference is nonzero and its valuation is $v_2(T) + b_j$, where b_j is the explicitly defined prefix bonus.

Source: `strengthening/formalization/DyadicFourLeastPeriods.lean`.

Lines 26–32; `KomorebiPaperIX.DyadicFourLeastPeriods.normalized_exact_displacement`.

```
theorem normalized_exact_displacement (j n T : ℕ) (hj : j < 4) (hT : 0 < T) :
    coeff 4 j (n + T) - coeff 4 j n ≠ 0 ∧
    padicValRat 2 (coeff 4 j (n + T) - coeff 4 j n) =
      (padicValNat 2 T : ℤ) + (DyadicFourPrefix.bonus j : ℤ) := by
  exact NewtonDominance.exact_displacement (coeff 4 j) (DyadicFourPrefix.bonus j)
    (DyadicFourPrefix.first_nonzero j hj) (DyadicFourPrefix.first_valuation j hj)
    (DyadicFourPrefix.tail_precision j hj) n T hT
```

Proof reading. The endpoint supplies four inputs to the generic Newton dominance theorem: first nonvanishing coefficient, its exact valuation, the strict tail-precision bound, and positivity of T. The conjunction records nonzero difference as well as valuation equality. At $T = 0$ the difference is zero, so the exact nonzero statement would be false. The theorem excludes that case.

The normalized bonus and the unnormalized bonus are distinguished. The latter incorporates the relevant factorial normalization. The exact-period classification is stated using the actual unnormalized sequence and its own bonus c_j.

Contract. A period in the source is a positive displacement. At precision r, the four-address unnormalized packet has period T exactly when $T > 0$ and $2^{\max(r - c_j, 0)} \mid T$. Natural subtraction in the source expresses the maximum with zero.

Source: `strengthening/formalization/DyadicFourLeastPeriods.lean`.

Lines 58–62; `KomorebiPaperIX.DyadicFourLeastPeriods.period_iff_dvd`.

```
theorem period_iff_dvd (j r T : ℕ) (hj : j < 4) :
    ExactPeriodClassification.IsPeriod 2 (unnormalized 4 j) r T ↔
      0 < T ∧ 2 ^ (r - originalBonus j) ∣ T :=
  ExactPeriodClassification.isPeriod_iff_dvd 2 (unnormalized 4 j)
    (originalBonus j) r T (fun n S hS => exact_displacement j n S hj hS)
```

Proof reading. Exact displacement reduces a universal congruence at every base row to an inequality $v_2(T) + c_j \geq r$. The generic classification translates that inequality into divisibility. If $r \leq c_j$, the exponent is zero and every positive displacement is a period. The least positive one is then one. If $r > c_j$, the least period is the indicated power of two. Zero remains excluded by the period predicate.

5.4 The normalized packet extends to a p-adic isometry

Contract. For $j < 4$, the appropriately rescaled rational packet extends uniquely to an isometric equivalence $\mathbb{Z}_2 \simeq \mathbb{Z}_2$ agreeing with its values at natural integers.

Source: `strengthening/formalization/DyadicFourIsometry.lean`.

Lines 78–84; `KomorebiPaperIX.DyadicFourIsometry.existsUnique_isometry`.

```
theorem existsUnique_isometry (j : ℕ) (hj : j < 4) :
    ∃! e : ℤ_[2] ≃ᵢ ℤ_[2], ∀ n : ℕ,
      (e (n : ℤ_[2]) : ℚ_[2]) = (DyadicPacketRational.packet j n : ℚ_[2]) := by
  refine ⟨isometry j hj, isometry_nat j hj, ?_⟩
  intro e he
  apply IsometryEquiv.ext
  exact congrFun (unique_continuous j hj e e.continuous he)
```

Proof reading. The source first constructs the isometry and proves agreement on natural inputs. Uniqueness then applies the theorem that continuous extensions agreeing on the dense natural subset agree everywhere. The isometric-equivalence conclusion includes surjectivity, so a merely distance-preserving embedding would not suffice. The rescaling and basepoint translation are part of the packet definition. The raw unnormalized sequence has a different image ball.

The concrete normalization is

$$(b_0, b_1, b_2, b_3) = (1, 1, 4, 2), \qquad (c_0, c_1, c_2, c_3) = (1, 1, 5, 3),$$

where b_j are normalized-coefficient bonuses and c_j are original-coefficient bonuses. Writing $U_{4,j}$ for the unnormalized packet, the isometric packet is

$$P_j(n) = \frac{U_{4,j}(n) - j!}{2^{c_j}}.$$

Its extension maps the unit ball onto the unit ball. Undoing that formula shows the original unnormalized extension has image $j! + 2^{c_j}\mathbb{Z}_2$.

This distinction explains the manuscript's affine-image consequence: undoing the normalization sends the unit ball to a specified affine residue ball. Neither the period theorem nor the isometry endpoint proves an unrestricted arithmetic statement for all moduli. Their exact hypotheses identify the four-address dyadic family being closed.

6 Finite obstructions and a common correction

6.1 Residuals become quotient classes

Let $A : \mathbb{Z}^d \to \mathbb{Z}^e$ be linear and suppose $Ax - b = p^L r$. A same-residue correction has the form $y = x + p^L t$. Its next residual is $p^L(r + At)$. Thus the next level exists precisely when $\bar{r} + \bar{A}\bar{t} = 0$ modulo p. The obstruction is the class of $\bar{r}$ in the cokernel of the digit map. Zero class means the residual can be cancelled by some digit.

Contract. The affine theorem requires $p > 0$, but neither primality nor $L \geq 1$. It supplies an integer residual, a finite obstruction space, and an equivalence between same-residue next-level lifts and zero obstruction.

Source: `polynomial_regularity/formalization/AffineObstructionCore.lean`.

Lines 152–171; `Komorebi.NativeAffine.finite_affine_obstruction`.

```
theorem finite_affine_obstruction (p L : ℕ) (hp : 0 < p)
    (A : (Fin d → ℤ) →ₗ[ℤ] (Fin e → ℤ)) (b : Fin e → ℤ) (x : Fin d → ℤ)
    (hx : ∀ i, (p : ℤ)^L ∣ (A x - b) i) :
    ∃ r : Fin e → ℤ,
      A x - b = (p : ℤ)^L • r ∧
      Finite (Obstruction p A) ∧
      ((∃ y : Fin d → ℤ,
        (∀ i, (p : ℤ)^L ∣ (y - x) i) ∧
        (∀ i, (p : ℤ)^(L+1) ∣ (A y - b) i)) ↔ obstruction p A r = 0) := by
  obtain ⟨r, hr⟩ := residual_exists p L A b x hx
  let : NeZero p := ⟨Nat.ne_of_gt hp⟩
  refine ⟨r, hr, obstruction_finite p A, ?_⟩
  rw [← affine_lift_iff_obstruction_zero p L hp A b r x hr]
  constructor
  · rintro ⟨y, hy, hAy⟩
    obtain ⟨t, rfl⟩ := (same_residue_iff ((p : ℤ)^L) x y).mp hy
    exact ⟨t, hAy⟩
  · rintro ⟨t, ht⟩
    exact ⟨x + (p : ℤ)^L • t,
      (same_residue_iff ((p : ℤ)^L) x _).mpr ⟨t, rfl⟩, ht⟩
```

Proof reading. Residual existence is coordinatewise integer divisibility. The source installs `NeZero p` to make the residue ring finite. It then rewrites arbitrary same-residue y as $x + p^L t$ using `same_residue_iff`. That rewriting supplies both directions: a successful lift gives a digit, and a successful digit constructs a lift. At $L = 0$, $p^L = 1$ and all integer points are in the same initial residue class. The affine calculation still works.

The finite quotient should not be confused with a rank formula. Finiteness over `ZMod p` works for any nonzero modulus. A dimension argument and the count $p^{d-\rho}$ need p prime so that the residue ring is a field.

Contract. Adding an image vector As to the residual does not change its obstruction class. No rank or surjectivity assumption is required.

Source: `polynomial_regularity/formalization/AffineObstructionCore.lean`.

Lines 70–79; `Komorebi.NativeAffine.obstruction_representative_independent`.

```
theorem obstruction_representative_independent (p : ℕ)
    (A : (Fin d → ℤ) →ₗ[ℤ] (Fin e → ℤ)) (r : Fin e → ℤ) (s : Fin d → ℤ) :
    obstruction p A (r + A s) = obstruction p A r := by
  change Submodule.Quotient.mk (reduction p e (r + A s)) = _
  rw [map_add, Submodule.Quotient.mk_add]
  have hs : (Submodule.Quotient.mk (reduction p e (A s)) : Obstruction p A) = 0 := by
    rw [Submodule.Quotient.mk_eq_zero]
    exact ⟨s, rfl⟩
  rw [hs, add_zero]
  rfl
```

Proof reading. The reduction map preserves addition. The quotient map then sends the reduced image vector to zero because it belongs to the digit-map range. Adding zero leaves the class unchanged. This is an exact statement about replacing a representative by a known image term. It does not establish the separate open problem of presentation invariance under every possible native equivalence.

6.2 Two solvable equations need one shared digit

For two maps A and B with separately soluble digit equations, choose individual correcting digits u and v. The first allows the coset $u + \ker \bar{A}$ and the second allows $v + \ker \bar{B}$. A common digit exists exactly when these cosets meet, equivalently when

$$u - v \in \ker \bar{A} + \ker \bar{B}.$$

The shared obstruction is the quotient of the common digit space by that sum. It is generally not the product of the two separate cokernels: those cokernels already vanish for the individually soluble pair, while the common-correction obstruction can still be nonzero.

Contract. Both chosen correcting digits must solve their own reduced residual equations. The theorem then identifies a joint next lift with equality of their classes in the shared quotient. Positivity of the modulus is retained. $L = 0$ is allowed.

Source: `polynomial_lifting/formalization/AffineSharedCorrection.lean`.

Lines 60–75; `Komorebi.AffinePair.joint_lift_iff_class_eq`.

```
theorem joint_lift_iff_class_eq (p L : ℕ) (hp : 0 < p)
    (A : (Fin d → ℤ) →ₗ[ℤ] (Fin e → ℤ))
    (B : (Fin d → ℤ) →ₗ[ℤ] (Fin f → ℤ))
    (b r : Fin e → ℤ) (c s : Fin f → ℤ) (x u v : Fin d → ℤ)
    (hr : A x - b = (p : ℤ)^L • r)
    (hs : B x - c = (p : ℤ)^L • s)
    (hu : reduction p e (r + A u) = 0)
    (hv : reduction p f (s + B v) = 0) :
    HasJointLift p L A B b c x ↔
    (Submodule.Quotient.mk u : SharedObstruction p A B) =
      Submodule.Quotient.mk v := by
  rw [joint_lift_iff_digit_correction p L hp A B b r c s x hr hs,
```

```
    quotient_mk_eq_iff_common]
  exact exists_congr fun t => and_congr
    (digit_correction_iff_same_image p A r u t hu)
    (digit_correction_iff_same_image p B s v t hv)
```

Proof reading. The first rewrite translates joint lifting into a simultaneous digit equation. The second identifies class equality with a common representative. The final `exists_congr` compares the two individual conditions by their image fibers. This separates the existence of separate corrections from their compatibility. A claim that separate solvability automatically gives a joint lift would drop the equality of quotient classes and is false.

Changing u by a digit in $\ker \bar{A}$ or changing v by one in $\ker \bar{B}$ leaves the shared class unchanged. The quotient has the expected universal property for maps annihilating both kernels, and its finite image/range formulations are proved in separate modules. Those endpoint statements retain their own exact coefficient conventions.

6.3 A nonempty fiber is a kernel torsor

Contract. $A : U \to V$ is linear over a ring, and a base point u has been supplied in the fiber over b. The fiber is equivalent to $\ker A$ by subtraction from u and translation back. The ambient U, V are modules and additive commutative groups.

Source: `polynomial_regularity/formalization/FiniteFiberCounts.lean`.

Lines 75–79; `Komorebi.FiniteFiberCounts.fiberEquivKernel`.

```
def fiberEquivKernel (A : U →ₗ[K] V) (b : V) (u : Fiber A b) : Fiber A b ≃ A.ker where
  toFun t := difference A b t u
  invFun v := translate A b v u
  left_inv t := translate_difference A b t u
  right_inv v := difference_translate A b v u
```

Proof reading. The forward map sends t to $t - u$ and uses linearity to prove it lies in the kernel. The inverse sends a kernel vector v to $u + v$ and proves its image is b. The two inverse identities are cancellation in the additive group. The chosen u is an origin for a torsor, not a distinguished zero of the original fiber. An empty fiber admits no such choice.

Contract. For a linear digit map $A : (\mathbb{F}_p)^d \to (\mathbb{F}_p)^e$ with rank ρ, the fiber over b has $p^{d-\rho}$ elements when nonempty and zero elements otherwise.

Source: `polynomial_regularity/formalization/FiniteFiberCounts.lean`.

Lines 138–144; `Komorebi.FiniteFiberCounts.fiber_card`.

```
theorem fiber_card (A : (Fin d → ZMod p) →ₗ[ZMod p] (Fin e → ZMod p))
    (b : Fin e → ZMod p) :
    Nat.card (Fiber A b) = if Nonempty (Fiber A b) then p ^ (d - rank p A) else 0 := by
  classical
  split_ifs with h
  · exact fiber_card_of_nonempty p A b h
  · exact fiber_card_of_empty A b h
```

Proof reading. The nonempty branch transports cardinality through the fiber–kernel equivalence and uses rank-nullity plus the finite-field cardinality theorem. The empty branch has cardinality zero. The `if Nonempty` guard cannot be discarded for a general right-hand side. In a surjective case every right-hand side enters the nonempty branch. In an injective square case the nonempty fiber has exactly one element.

7 Actual polynomial Taylor expansion and lift counts

7.1 A quadratic remainder is proved algebraically

Contract. P is an actual multivariate polynomial with integer coefficients, $x, t \in \mathbb{Z}^d$, and $a \in \mathbb{Z}$. The directional derivative uses the evaluated formal partial derivatives. Then a^2 divides $P(x+at) - P(x) - aDP(x)t$.

Source: `polynomial_regularity/formalization/PolynomialTaylor.lean`.

Lines 41–53; `Komorebi.PolynomialTaylor.taylor_dvd`.

```
theorem taylor_dvd {d : ℕ} (P : MvPolynomial (Fin d) ℤ)
    (x t : Fin d → ℤ) (a : ℤ) :
    a ^ 2 | eval (fun i => x i + a * t i) P - eval x P - a * directional P x t := by
  induction P using MvPolynomial.induction_on with
  | C c => simp [directional]
  | add P Q hP hQ =>
    simp only [map_add, directional_add]
    convert dvd_add hP hQ using 2 <;> first | rfl | ring
  | mul_X P j hP =>
    obtain ⟨r, hr⟩ := hP
    refine ⟨r * (x j + a * t j) + directional P x t * t j, ?_⟩
    simp only [map_mul, eval_X, directional_mul, directional_X]
    linear_combination (x j + a * t j) * hr
```

Proof reading. The proof inducts on the multivariate polynomial syntax supplied by Mathlib: a constant, an addition, or multiplication by a variable. Constants have zero remainder. Sums add remainders. In the multiplication case, the induction witness r is combined with the linear term and the new variable displacement. `linear_combination` verifies the resulting polynomial identity. This is exact integer algebra and requires no differentiability or limiting argument.

The quadratic factor is what permits one-digit lifting. Put $a = q^L$. The remainder is divisible by q^{2L}. To neglect it modulo q^{L+1}, one needs $2L \geq L + 1$, hence $L \geq 1$. An affine map has no quadratic remainder and works at $L = 0$. A general polynomial does not. The source does not assume that an arbitrary nonlinear map comes with the same exact expansion.

7.2 One nonlinear step becomes a finite digit equation

Write $F(x) = q^L r$ coordinatewise. The actual Jacobian $J_F(x)$ is defined by formal partial derivatives evaluated at x, assembled as an integer linear map. The next-level equation is

$$F(x + q^L t) \equiv 0 \pmod{q^{L+1}} \quad \Longleftrightarrow \quad r + J_F(x)t \equiv 0 \pmod{q}.$$

Contract. $q > 0$, $L \geq 1$, and the given residual identity is exact. No prime assumption is needed for this equivalence.

Source: `polynomial_regularity/formalization/PolynomialObstruction.lean`.

Lines 97–108; `Komorebi.PolynomialObstruction.next_level_iff_digit`.

```
theorem next_level_iff_digit (q L : ℕ) (hq : 0 < q) (hL : 1 ≤ L)
    (F : Fin e → MvPolynomial (Fin d) ℤ) (x : Fin d → ℤ)
    (r : Fin e → ℤ) (hr : evalSystem F x = (q : ℤ)^L • r)
    (t : Fin d → ℤ) :
    (∀ i, (q : ℤ)^(L+1) | evalSystem F (x + (q : ℤ)^L • t) i) ↔
      reduction q e (r + jacobian F x t) = 0 := by
  rw [reduction_zero_iff]
  apply forall_congr'
  intro i
  rw [dvd_iff_of_dvd_sub _ _ _ (taylor_residual_dvd q L hL F x r hr t i)]
  have hqL : (q : ℤ)^L ≠ 0 := pow_ne_zero _ (Int.natCast_ne_zero.mpr (Nat.ne_of_gt hq))
  rw [pow_succ, mul_dvd_mul_iff_left hqL]
```

Proof reading. The source rewrites reduced zero as coordinatewise divisibility. Taylor remainder divisibility replaces the actual polynomial value by its residual-plus-linear term. The remaining factor q^L can be cancelled because $q > 0$ implies $q^L \neq 0$ in $\mathbb{Z}$. This cancellation gives the modulo-q equation. Both directions are proved, so the linearization is an exact next-digit criterion rather than an approximation.

Contract. The finite polynomial obstruction theorem starts with an approximate root modulo q^L and constructs its residual. The obstruction space uses the range of the actual Jacobian digit map.

Source: `polynomial_regularity/formalization/PolynomialObstruction.lean`.

Lines 141–154; `Komorebi.PolynomialObstruction.finite_polynomial_obstruction`.

```
theorem finite_polynomial_obstruction (q L : ℕ) (hq : 0 < q) (hL : 1 ≤ L)
    (F : Fin e → MvPolynomial (Fin d) ℤ) (x : Fin d → ℤ)
    (hx : ∀ i, (q : ℤ)^L | evalSystem F x i) :
    ∃ r : Fin e → ℤ,
      evalSystem F x = (q : ℤ)^L • r ∧
      Finite (Obstruction q (jacobian F x)) ∧
      ((∃ y : Fin d → ℤ,
        (∀ i, (q : ℤ)^L | (y - x) i) ∧
        (∀ i, (q : ℤ)^(L+1) | evalSystem F y i)) ↔
          obstruction q (jacobian F x) r = 0) := by
  obtain ⟨r, hr⟩ := residual_exists q L F x hx
  let : NeZero q := ⟨Nat.ne_of_gt hq⟩
  exact ⟨r, hr, obstruction_finite q (jacobian F x),
    polynomial_same_residue_lift_iff q L hq hL F x r hr⟩
```

Proof reading. Residual existence supplies r. The finite quotient construction is reused from the affine layer, while the polynomial same-residue theorem supplies the nonlinear lifting equivalence. Reusing the quotient algebra does not require treating the polynomial as affine. Its application is justified precisely at this one-digit Taylor interface.

A nonzero obstruction means no same-residue next lift exists. A zero obstruction proves existence for that step. It does not by itself prove persistence at all later depths: the Jacobian and the residual may change, and singular digit maps can develop higher obstructions. The smooth tower theorem adds surjectivity and proves it persists along the constructed tower.

7.3 Digits correspond to residue lifts, not all integer representatives

The lift-counting development distinguishes an integer lift from its residue class modulo p^{L+1}. Without that quotient, a soluble congruence has infinitely many integer representatives. `ActualLifts` is a finite type of residue lifts, and `DigitSolutions` is the finite fiber of the digit equation.

Contract. $q > 0$, $L \geq 1$, and $F(x) = q^L r$. The residue digit equivalence takes a digit solution modulo q to a residue lift modulo q^{L+1}.

Source: `polynomial_regularity/formalization/PolynomialLiftCounts.lean`.

Lines 43–48; `Komorebi.PolynomialLiftCounts.digitEquivLifts`.

```
def digitEquivLifts (q L : ℕ) (hq : 0 < q) (hL : 1 ≤ L)
    (F : Fin e → MvPolynomial (Fin d) ℤ) (x : Fin d → ℤ)
    (r : Fin e → ℤ) (hr : evalSystem F x = (q : ℤ)^L • r) :
    DigitSolutions q F x r ≃ ActualLifts q L F x :=
  Equiv.subtypeEquiv (digitEquivResidue q L hq x)
    (fun t => (digit_residue_solution_iff q L hq hL F x r hr t).symm)
```

Proof reading. The source first has an equivalence between all digit addresses and all residue addresses above the initial class. `Equiv.subtypeEquiv` then restricts it to the subsets satisfying the equations. The previous next-digit theorem supplies the required equivalence of predicates. Thus cardinalities are preserved through a genuinely bijective map. A mere surjection would not establish the exact count.

Contract. Now p is prime. If the digit Jacobian has rank ρ, the number of residue lifts is zero for nonzero obstruction and $p^{d-\rho}$ for zero obstruction. The obstruction space has $p^{e-\rho}$ elements.

Source: `polynomial_regularity/formalization/PolynomialLiftCounts.lean`.

Lines 104–115; `Komorebi.PolynomialLiftCounts.finite_polynomial_lift_count`.

```
theorem finite_polynomial_lift_count (p L : ℕ) [Fact (Nat.Prime p)] (hL : 1 ≤ L)
    (F : Fin e → MvPolynomial (Fin d) ℤ) (x : Fin d → ℤ)
    (hx : ∀ i, (p : ℤ)^L | evalSystem F x i) :
    ∃ r : Fin e → ℤ,
      evalSystem F x = (p : ℤ)^L • r ∧
      Nat.card (ActualLifts p L F x) =
        (if obstruction p (jacobian F x) r = 0 then
          p ^ (d - FiniteFiberCounts.rank p (digitJacobian p F x)) else 0) ∧
      Nat.card (Obstruction p (jacobian F x)) =
        p ^ (e - FiniteFiberCounts.rank p (digitJacobian p F x)) := by
  obtain ⟨r, hr⟩ := Komorebi.PolynomialObstruction.residual_exists p L F x hx
  exact ⟨r, hr, lift_card p L hL F x r hr, obstruction_card p F x⟩
```

Proof reading. The endpoint reuses the digit–lift equivalence for the lift cardinality and the finite cokernel equivalence for the obstruction cardinality. Rank-nullity yields the two exponents in the input and output spaces respectively. The rank is bounded by both d and e, so natural subtraction expresses the ordinary nonnegative dimension difference in these hypotheses. Rectangular equations can have many lifts even when every obstruction vanishes.

At a surjective digit Jacobian, $\rho = e$ and each step has p^{d-e} residue lifts. When $d = e$, that number is one. This is the source of both smooth existence and square-case uniqueness. When $d > e$, existence is still valid but a claim of unique solved coordinates would discard the nontrivial kernel.

8 Compatible integer towers and p-adic endpoints

8.1 The tower is constructed, not supplied

Contract. $q > 0$, $L \geq 1$, F has integer coefficients, the starting point is a root modulo q^L, and its digit Jacobian over `ZMod q` is surjective. The theorem constructs a whole sequence z_n of integer points.

Source: `polynomial_regularity/formalization/PolynomialIntegerTower.lean`.

Lines 80–96; `Komorebi.PolynomialIntegerTower.exists_compatible_tower_strong`.

```
theorem exists_compatible_tower_strong (q L : ℕ) (hq : 0 < q) (hL : 1 ≤ L)
    (F : Fin e → MvPolynomial (Fin d) ℤ) (x : Fin d → ℤ)
    (hx : ∀ i, (q : ℤ)^L | evalSystem F x i)
    (hJ : Function.Surjective (digitJacobian q F x)) :
    ∃ z : ℕ → Fin d → ℤ,
      z 0 = x ∧
      (∀ n i, (q : ℤ)^(L+n) | evalSystem F (z n) i) ∧
      (∀ n i, (q : ℤ)^(L+n) | (z (n+1) - z n) i) ∧
      (∀ m n, m ≤ n → ∀ i, (q : ℤ)^(L+m) | (z n - z m) i) ∧
      (∀ n, digitJacobian q F (z n) = digitJacobian q F x) ∧
      (∀ n, Function.Surjective (digitJacobian q F (z n))) := by
  obtain ⟨z, hz0, hroot, hstep, hsurj⟩ := exists_compatible_tower q L hq hL F x hx hJ
  refine ⟨z, hz0, hroot, hstep, ?_, ?_, hsurj⟩
  · exact fun m n hmn => tower_pairwise_congruent q L z hstep m n hmn
  · intro n
    rw [← hz0]
    exact tower_digitJacobian_eq q L hL F z hstep n
```

The theorem returns six pieces of information together. It fixes $z_0 = x$. $F(z_n)$ vanishes modulo q^{L+n}. Successive points differ by multiples of q^{L+n}. Every later point agrees with an earlier point to that earlier depth. The digit Jacobian stays equal to the starting one. Surjectivity holds at every level. These statements keep existence, compatibility and smoothness separate.

Proof reading. The basic tower theorem chooses a correcting digit at each step using digit-map surjectivity. The stronger endpoint adds pairwise congruence by summing compatible increments and identifies every digit Jacobian with the initial map. Polynomial partial derivatives have integer coefficients, so same residue modulo q gives the same reduced derivative. Since $L \geq 1$, all constructed points stay in that initial residue class.

The construction is allowed to use classical choice. It proves an actual infinite sequence in the mathematical model, but it is not presented as extracted executable code. A finite loop that finds digits for a few depths is useful bounded evidence. It does not replace the compatible-tower theorem.

8.2 Completeness changes the coefficient domain

For a prime p, cast z_n coordinatewise into $\mathbb{Z}_p$. Pairwise congruence at depths tending to infinity makes the sequence Cauchy in each coordinate. Finite products of complete spaces are complete, so the vector sequence converges to a p-adic point b.

Contract. p is prime, $L \geq 1$, and the same initial root and surjectivity hypotheses hold. The theorem returns the integer tower, its p-adic limit, an exact polynomial root, and the retained congruence of the limit to every tower stage.

Source: polynomial_regularity/formalization/PolynomialPadicLift.lean.

Lines 57–77; Komorebi.PolynomialPadicLift.exists_padic_root_with_tower.

```
theorem exists_padic_root_with_tower (p L : ℕ) [Fact (Nat.Prime p)] (hL : 1 ≤ L)
    (F : Fin e → MvPolynomial (Fin d) ℤ) (x : Fin d → ℤ)
    (hx : ∀ i, (p : ℤ)^L | evalSystem F x i)
    (hJ : Function.Surjective (digitJacobian p F x)) :
    ∃ z : ℕ → Fin d → ℤ, ∃ a : Fin d → ℤ_[p],
      z 0 = x ∧
      (∀ n i, (p : ℤ)^(L+n) | evalSystem F (z n) i) ∧
      (∀ n i, (p : ℤ)^(L+n) | (z (n+1) - z n) i) ∧
      Tendsto (fun n i => (z n i : ℤ_[p])) atTop (𝓝 a) ∧
      (∀ n i, (p : ℤ_[p])^(L+n) | a i - (z n i : ℤ_[p])) ∧
      (∀ i, padicEval p F a i = 0) ∧
      (∀ n, digitJacobian p F (z n) = digitJacobian p F x) ∧
      (∀ n, Nat.card (PolynomialLiftCounts.ActualLifts p (L+n) F (z n)) = p^(d-e)) := by
  obtain ⟨z, hz0, hroot, hstep, _, hcount⟩ := exists_regular_tower p L hL F x hx hJ
  obtain ⟨a, ha, hprecision⟩ :=
    PadicTowerLimit.compatible_vector_tower_limit p L z hstep
  refine ⟨z, a, hz0, hroot, hstep, ha, hprecision,
    polynomial_tower_limit_root p L F z a hroot ha, ?_, hcount⟩
  intro n
  rw [← hz0]
  exact tower_digitJacobian_eq p L hL F z hstep n
```

Proof reading. The source combines the integer tower theorem with the general p-adic tower-limit theorem. Polynomial evaluation is continuous, so $F(z_n)$ converges to $F(b)$. Its divisibility by arbitrarily large powers of p forces its limit to zero. A fixed-depth congruence ball is closed, yielding the stronger precision statement $p^{L+n} \mid b - z_n$ for each fixed n.

This proof separates two limiting operations. Compatibility controls the input limit. Increasing residual depth controls the output limit. Neither alone suffices: a convergent sequence of approximate points whose residual depth does not increase need not converge to an exact root.

8.3 Uniqueness requires a square solved system

Contract. The p-adic unique-root endpoint uses d equations in d unknowns and a surjective digit Jacobian, hence a bijective digit map over $\mathbb{F}_p$. It asserts uniqueness only in the initial depth-L residue ball.

Source: polynomial_regularity/formalization/PolynomialPadicUnique.lean.

Lines 146–156; Komorebi.PolynomialPadicUnique.exists_unique_padic_root.

```
theorem exists_unique_padic_root (p L : ℕ) [Fact (Nat.Prime p)] (hL : 1 ≤ L)
    (F : Fin d → MvPolynomial (Fin d) ℤ) (x : Fin d → ℤ)
    (hx : ∀ i, (p : ℤ)^L | evalSystem F x i)
    (hJ : Function.Surjective (digitJacobian p F x)) :
    ∃! a : Fin d → ℤ_[p],
      (∀ i, MvPolynomial.eval₂ (Int.castRingHom ℤ_[p]) a (F i) = 0) ∧
      (∀ i, (p : ℤ_[p])^L | a i - (x i : ℤ_[p])) := by
  obtain ⟨a, ha, hax⟩ := exists_padic_root p L hL F x hx hJ
```

```
refine ⟨a, ⟨ha, hax⟩, ?_⟩
intro b hb
exact padic_root_unique p L hL F x hJ b a hb.1 ha hb.2 hax
```

Proof reading. Existence supplies one root. The uniqueness theorem compares any second root with that root by finite residues. At each successive depth, the digit equation has exactly one solution, so equal residues at the current depth imply equal residues at the next. Equality at all depths forces equality in $\mathbb{Z}_p$. The excerpt packages that comparison into `∃!`.

The uniqueness proof uses actual finite reductions of arbitrary p-adic roots, not an assumption that every candidate arose from the chosen integer tower. That distinction matters: uniqueness must quantify over every root in the specified ball. For a rectangular surjective system, the kernel has positive dimension and the same conclusion is generally false. The retained rectangular-uniqueness negative control guards this boundary.

8.4 Coefficient stability retains the promised precision

The deformation modules also compare a polynomial system with a coefficientwise congruent perturbation in the smooth, unit-Jacobian setting. Because evaluation preserves coefficient congruence at integral points, the original approximate root is an approximate root of the perturbed system. Its reduced Jacobian is unchanged when the coefficient perturbation has positive depth. The same smooth root theorem gives a nearby root, and the uniqueness comparison fixes the promised residue precision.

This reasoning supplies a bound at the declared perturbation depth. It does not imply an additional free digit. A linear equation with its constant term shifted by exactly p^M has its root shifted by exactly that precision. The retained `InvalidPerturbationExtraPrecision` control is based on that obstruction to strengthening the bound.

9 Local charts and prescribed parameter paths

9.1 The solved block is the correct Jacobian

Split the variables as (y, t), where y has m solved coordinates and t has k prescribed parameters. For e equations the reduced Jacobian has blocks

$$DF = (J\ K), \qquad J : \mathbb{F}_p^m \to \mathbb{F}_p^e, \quad K : \mathbb{F}_p^k \to \mathbb{F}_p^e.$$

A prescribed parameter digit v changes the residual by Kv. The solved digit u must solve

$$Ju = -\bar{r} - Kv.$$

Surjectivity of the full matrix $(J\ K)$ is insufficient when v has already been fixed. It is surjectivity of J that permits every prescribed digit.

Contract. For an integer polynomial system, the source defines the parameter residual $\bar{r} + Kv$, the solved digit map J, and the joined full digit (u, v). The split equation equals the full digit equation exactly.

Source: `polynomial_regularity/formalization/PolynomialPrescribedSystem.lean`.

Lines 77–82; `Komorebi.PolynomialPrescribedSystem.prescribed_equation_iff`.

```
theorem prescribed_equation_iff (q : ℕ) (F : Fin e → MvPolynomial (Fin (m + k)) ℤ)
    (x : Fin (m + k) → ℤ) (r : Fin e → ℤ) (v : Fin k → ZMod q) (u : Fin m → ZMod q) :
    parameterResidual q F x r v + solvedJacobian q F x u = 0 ↔
      reduction q e r + digitJacobian q F x (PolynomialParameterSystem.join u v) = 0 := by
  rw [digitJacobian_join]
  simp only [parameterResidual, add_assoc, add_comm (parameterJacobian q F x v)]
```

Proof reading. The block derivative theorem rewrites the full digit map on `join u v` as the sum of the solved and parameter actions. Associativity and commutativity then identify the residual equations. The parameter term has positive sign inside $\bar{r} + Kv + Ju = 0$, and consequently negative sign when solving for u. Losing this sign changes the actual root motion.

If the solved block has rank ρ, a soluble prescribed-digit fiber has $p^{m-\rho}$ elements. For a surjective J, this becomes p^{m-e} for every prescribed v. A square solved block gives one solved digit for each parameter digit. Rectangular solved blocks leave free solved directions, so prescribing the parameter alone does not generally select one root.

9.2 The continuous chart includes both directions

Contract. The chart endpoint uses e equations, e solved coordinates and q free parameters. The starting integer point is a root modulo p^L, $L \geq 1$, and the solved digit Jacobian is surjective. The homeomorphism is between the parameter residue ball and the exact root locus in the full residue ball.

Source: `polynomial_regularity/formalization/PolynomialParameterChart.lean`.

Lines 167–183; `Komorebi.PolynomialParameterChart.parameterHomeomorph`.

```
def parameterHomeomorph (p L : ℕ) [Fact (Nat.Prime p)] (hL : 1 ≤ L)
    (F : Fin e → MvPolynomial (Fin (e + q)) ℤ) (x : Fin (e + q) → ℤ)
    (hx : ∀ i, (p : ℤ)^L | evalSystem F x i)
    (hJ : Function.Surjective (solvedJacobian p F x)) :
    residueBall p L (freePart x) ≃ₜ {z : residueBall p L x // padicEval p F z.val = 0} where
  toFun t := ⟨chartPoint p L hL F x hx hJ t, chartPoint_root p L hL F x hx hJ t⟩
  invFun z := ⟨freePart z.val.val, fun j => z.val.property (Fin.natAdd e j)⟩
  left_inv t := Subtype.ext (chartPoint_free p L hL F x hx hJ t)
  right_inv z := by
    apply Subtype.ext
    exact (chartPoint_unique p L hL F x hx hJ _ z.val z.property rfl).symm
  continuous_toFun := by
    apply Continuous.subtype_mk
    exact continuous_chartPoint p L hL F x hx hJ
  continuous_invFun := by
    apply Continuous.subtype_mk
    exact continuous_freePart.comp (continuous_subtype_val.comp continuous_subtype_val)
```

Proof reading. The forward map takes a parameter to its uniquely solved root in the ball. The inverse is the free-coordinate projection. The first inverse identity says the constructed root has the requested parameter. The second invokes uniqueness of solved coordinates for any root in the ball. Continuity of the solution map and continuity of the projection establish a homeomorphism, not merely a set bijection.

This chart has explicit integral residue balls and strong congruence control. Its source proof precedes the analytic regularity layer. A homeomorphism of root spaces does not automatically identify an analytic derivative. The later polynomial/analytic bridge supplies that stronger conclusion under fraction-field nonsingularity.

9.3 An arbitrary p-adic parameter is reached by integer digits

The prescribed tower construction can begin with a supplied compatible integer parameter path t_n converging to τ. It constructs solved coordinates at every depth and tracks the actual parameter path, rather than guessing compatible roots independently. The endpoint also builds such a parameter path for every p-adic τ in the initial parameter ball.

Contract. p is prime, $L \geq 1$, J is the surjective solved digit map with m solved coordinates and e equations, and τ lies in the initial parameter residue ball. No solution tower or parameter path is an input to this endpoint.

Source: `polynomial_regularity/formalization/PolynomialPrescribedPadicTower.lean`.

Lines 57–76; `Komorebi.PolynomialPrescribedPadicTower.exists_prescribed_padic_root_with_tower`.

```
theorem exists_prescribed_padic_root_with_tower (p L : ℕ) [Fact (Nat.Prime p)]
    (hL : 1 ≤ L) (F : Fin e → MvPolynomial (Fin (m+k)) ℤ)
    (x : Fin (m+k) → ℤ) (hx : ∀ i, (p : ℤ)^L | evalSystem F x i)
    (hJ : Function.Surjective (solvedJacobian p F x))
    (τ : Fin k → ℤ_[p])
```

```
    (hτ : ∀ j, (p : ℤ_[p])^L | τ j - ((freePart x j : ℤ) : ℤ_[p])) :
    ∃ (z : ℕ → Fin (m+k) → ℤ) (b : Fin (m+k) → ℤ_[p]),
      z 0 = x ∧
      (∀ n i, (p : ℤ)^(L+n) | evalSystem F (z n) i) ∧
      (∀ n i, (p : ℤ)^(L+n) | (z (n+1) - z n) i) ∧
      (∀ n, solvedJacobian p F (z n) = solvedJacobian p F x) ∧
      Tendsto (fun n i => (z n i : ℤ_[p])) atTop (𝓝 b) ∧
      (∀ i, padicEval p F b i = 0) ∧ freePart b = τ ∧
      (∀ n i, (p : ℤ_[p])^(L+n) | b i - (z n i : ℤ_[p])) ∧
      (∀ n v, Nat.card (PrescribedLifts p (L+n) F (z n) v) = p^(m-e)) := by
  obtain ⟨t, ht0, ht, _, htlim⟩ :=
    PolynomialParameterPath.exists_parameter_path p L (freePart x) τ hτ
  obtain ⟨z, b, hz0, _, hroot, hstep, hfixed, hlim, hb, hbτ, hprecision, hcard⟩ :=
    exists_root_with_prescribed_path p L hL F x hx hJ t ht0 ht τ htlim
  exact ⟨z, b, hz0, hroot, hstep, hfixed, hlim, hb, hbτ, hprecision, hcard⟩
```

Proof reading. The parameter-path theorem supplies integer approximations with the correct initial value and increment divisibility. The prescribed integer tower fills in solved digits using J-surjectivity. A p-adic tower limit then gives the exact root with free part τ. The returned finite lift count p^{m-e} holds at every stage and for every next parameter digit, making the rectangular freedom explicit.

Contract. For $m = e$, the prescribed root in the initial ball is unique. The full predicate includes its exact parameter τ as well as its root equation and residue ball.

Source: `polynomial_regularity/formalization/PolynomialPrescribedPadicTower.lean`.

Lines 96–109; `Komorebi.PolynomialPrescribedPadicTower.exists_unique_prescribed_padic_root`.

```
theorem exists_unique_prescribed_padic_root (p L : ℕ) [Fact (Nat.Prime p)]
    (hL : 1 ≤ L) (F : Fin e → MvPolynomial (Fin (e+k)) ℤ)
    (x : Fin (e+k) → ℤ) (hx : ∀ i, (p : ℤ)^L | evalSystem F x i)
    (hJ : Function.Surjective (solvedJacobian p F x))
    (τ : Fin k → ℤ_[p])
    (hτ : ∀ j, (p : ℤ_[p])^L | τ j - ((freePart x j : ℤ) : ℤ_[p])) :
    ∃! b : Fin (e+k) → ℤ_[p],
      (∀ i, padicEval p F b i = 0) ∧ freePart b = τ ∧
      (∀ i, (p : ℤ_[p])^L | b i - (x i : ℤ_[p])) := by
  obtain ⟨b, hb, hbτ, hbx⟩ := exists_prescribed_padic_root p L hL F x hx hJ τ hτ
  refine ⟨b, ⟨hb, hbτ, hbx⟩, ?_⟩
  intro c hc
  exact PolynomialPrescribedTowerUnique.prescribed_root_unique p L hL F x hx hJ
    c b hc.1 hb hc.2.2 hbx (hc.2.1.trans hbτ.symm)
```

Proof reading. Existence and the prescribed-root comparison theorem are combined. Two candidates with the same parameter have zero parameter difference, so their next solved digit difference lies in the kernel of the bijective solved block. It vanishes at each depth. The theorem therefore controls every candidate root with that parameter, independent of the tower choices used to obtain the first one.

If $k = 0$, the parameter space has one vector and the theorem reduces to the square root theorem. If there are zero equations, the algebraic finite-product statements remain meaningful in dimension zero, subject to their stated typeclass and surjectivity hypotheses. The source does not impose a positive dimension merely to make a matrix display look conventional.

9.4 A full-rank system admits a suitable coordinate split

For a general e-equation system with surjective full reduced Jacobian, the minor-selection module chooses e independent columns. The coordinate-reordering module turns that choice into a permutation separating solved and free coordinates. It proves evaluation and derivative blocks transform according to that actual permutation. The general-chart theorem then applies the square solved-block chart in those coordinates and transports the result back.

This is existence of a good coordinate split. It does not assert that every externally prescribed split has a surjective solved block. If a parameter policy has already fixed particular coordinates, its prescribed-lifting theorem must still check that policy's own solved block. The finite dimensions and explicit reorder equivalence preserve the number of free parameters, $d - e$.

10 Weighted inverse bounds and quantitative root motion

10.1 A fraction-field bound has an integral certificate

Let J be the actual square Jacobian at an integral p-adic center. It may be singular modulo p while remaining invertible over $\mathbb{Q}_p$. The relevant size condition is that $p^s J^{-1}$ is an integral matrix. This condition records the chosen exponent s directly. The proof does not replace it by a possibly larger determinant valuation.

Contract. p is prime and s is natural. Fraction-field invertibility together with an integral matrix representing $p^s J^{-1}$ is equivalent to an integral two-sided certificate $AJ = JA = p^s I$.

Source: `polynomial_regularity/formalization/PolynomialWeightedInverse.lean`.

Lines 142–155; `Komorebi.PolynomialWeightedInverse.bounded_inverse_iff_certificate`.

```
theorem bounded_inverse_iff_certificate (p s : ℕ) [Fact (Nat.Prime p)]
    (J : Matrix (Fin d) (Fin d) ℤ_[p]) :
    (IsUnit (rationalMatrix p J) ∧
      ∃ A : Matrix (Fin d) (Fin d) ℤ_[p],
        rationalMatrix p A = (p : ℚ_[p])^s • (rationalMatrix p J)⁻¹) ↔
    (∃ A : Matrix (Fin d) (Fin d) ℤ_[p],
      A * J = (p : ℤ_[p])^s • (1 : Matrix (Fin d) (Fin d) ℤ_[p]) ∧
      J * A = (p : ℤ_[p])^s • (1 : Matrix (Fin d) (Fin d) ℤ_[p])) := by
  constructor
  · rintro ⟨hJ, hA⟩
    exact (integral_inverse_iff_certificate p s J hJ).mp hA
  · rintro ⟨A, hAJ, hJA⟩
    have hJ := rationalMatrix_isUnit_of_certificate p s J A hAJ
    exact ⟨hJ, (integral_inverse_iff_certificate p s J hJ).mpr ⟨A, hAJ, hJA⟩⟩
```

Proof reading. The embedding of integral matrices into rational p-adic matrices preserves multiplication and scalar action. An integral representation of the inverse therefore gives the two identities after injectivity of the embedding. Conversely, the two-sided identities establish invertibility in the fraction field because $p^s \neq 0$. Both products matter: they support normalization and root equivalence in different directions. A single entrywise valuation statement without an actual matrix inverse is not this certificate.

10.2 Polynomial maps become contractions after scaling

Integral polynomial evaluation is Lipschitz for the p-adic sup metric. Multiplying it by p yields a strict contraction. The contraction map has the form $u \mapsto c + pH(u)$, so the fixed point theorem acts on the complete space of integral p-adic vectors.

Contract. H is an arbitrary vector of actual multivariate polynomials with $\mathbb{Z}_p$ coefficients and $c \in \mathbb{Z}_p^d$. The source establishes a unique fixed point of its specified contraction map.

Source: `polynomial_regularity/formalization/PolynomialPadicContraction.lean`.

Lines 101–105; `Komorebi.PolynomialPadicContraction.exists_unique_fixedPoint`.

```
theorem exists_unique_fixedPoint (p : ℕ) [Fact p.Prime]
    (H : Fin d → MvPolynomial (Fin d) ℤ_[p]) (c : Fin d → ℤ_[p]) :
```

```
    ∃! u : Fin d → ℤ_[p], contractionMap p H c u = u := by
  let hf := contracting_contractionMap p H c
  exact ⟨hf.fixedPoint _, hf.fixedPoint_isFixedPt, fun u hu => hf.fixedPoint_unique hu⟩
```

Proof reading. The source first proves the Lipschitz estimate for polynomial evaluation and the contraction constant after multiplication by p. `contracting_contractionMap` packages that estimate into the complete-space fixed point machinery. The final three fields are the fixed point, its fixed-point equation, and uniqueness against every other fixed point. The source's separate divisible-fixed-point theorem controls precision when c has a specified p-power factor and $H(0) = 0$.

The condition $H(0) = 0$ is required for that additional precision argument for divisible fixed points. It is not a requirement of the bare fixed-point existence theorem displayed above. Keeping these two contracts separate prevents an accidental strengthening.

10.3 The threshold and the uniqueness ball are explicit

For $F(a)$ divisible by p^r and a certificate exponent s, the source imposes $r > 2s$. Write $b = a + p^{s+1}u$. Actual polynomial Taylor expansion and preconditioning put the equation into the normalized form

$$p^{2s+1}(C + u + pQ(u)) = 0, \qquad Q(0) = 0, \qquad p^{r-(2s+1)} \mid C.$$

The contraction solves for u, and its precision transfers back to b.

Contract. F is square with integral p-adic coefficients; $J_F(a)$ is invertible over $\mathbb{Q}_p$; $p^s J_F(a)^{-1}$ is integral; $F(a)$ is divisible by p^r; and $r > 2s$. The root is unique in the entire depth-$s+1$ ball and is congruent to a to depth $r - s$.

Source: `polynomial_regularity/formalization/PolynomialWeightedLift.lean`.

Lines 112–125; `Komorebi.PolynomialWeightedLift.exists_weighted_root`.

```
theorem exists_weighted_root (p s r : ℕ) [Fact p.Prime]
    (hr : 2 * s < r) (F : Fin d → MvPolynomial (Fin d) ℤ_[p])
    (a : Fin d → ℤ_[p]) (hJ : IsUnit (rationalMatrix p (jacobian F a)))
    (hbound : ∃ A : Matrix (Fin d) (Fin d) ℤ_[p],
      rationalMatrix p A = (p : ℚ_[p]) ^ s • (rationalMatrix p (jacobian F a))⁻¹)
    (hF : ∀ i, (p : ℤ_[p]) ^ r ∣ eval a (F i)) :
    ∃ b : Fin d → ℤ_[p],
      (∀ i, eval b (F i) = 0) ∧
      (∀ i, (p : ℤ_[p]) ^ (r - s) ∣ b i - a i) ∧
      (∀ i, (p : ℤ_[p]) ^ (s + 1) ∣ b i - a i) ∧
      (∀ z : Fin d → ℤ_[p], (∀ i, eval z (F i) = 0) →
        (∀ i, (p : ℤ_[p]) ^ (s + 1) ∣ z i - a i) → z = b) := by
  obtain ⟨A, hAJ, hJA⟩ := (bounded_inverse_iff_certificate p s (jacobian F a)).mp ⟨hJ, hbound⟩
  exact exists_weighted_root_certificate p s r hr F a A hAJ hJA hF
```

Proof reading. The source converts the fraction-field bound to the integral two-sided certificate. Its normalization theorem builds C, Q from the actual polynomials, so no Taylor expansion or contraction hypothesis is supplied by the caller. The normalized-root theorem obtains the fixed point and transfers its root equation, precision, and uniqueness back to the original coordinates. The root-equivalence step uses injectivity of the preconditioner in the fraction field.

At the least permitted depth $r = 2s + 1$, the precision $r - s = s + 1$ is exactly the uniqueness-ball depth. Larger r improves the retained root precision. The boundary $r = 2s$ is excluded. The retained weighted-boundary counterexample supplies an integral polynomial with that residual depth and no integral root. A linear example also shows the loss of s in the displacement is sharp. Thus neither replacing $>$ by $\geq$ nor adding a free precision digit follows from this theorem.

10.4 Coefficient perturbation has a first-order formula

Suppose $F(a) = 0$ and perturb the actual coefficient system to $F + p^M H$, with $M > 2s$. The same original inverse certificate supports the nearby root. The derivative of the perturbation is handled in the proof, rather than assumed to have exactly the old inverse.

Contract. The perturbed root is unique in the depth-$s + 1$ ball, has displacement divisible by p^{M-s}, and its rational p-adic first-order term is $-p^M J_F(a)^{-1} H(a)$. The integral error has depth $2M - 3s$.

Source: `polynomial_regularity/formalization/PolynomialRootMotion.lean`.

Lines 142–162; `Komorebi.PolynomialRootMotion.exists_unique_root_motion`.

```
theorem exists_unique_root_motion (p s M : ℕ) [Fact p.Prime]
    (hM : 2 * s < M) (F H : Fin d → MvPolynomial (Fin d) ℤ_[p])
    (a : Fin d → ℤ_[p]) (hFa : ∀ i, eval a (F i) = 0)
    (hJ : IsUnit (rationalMatrix p (jacobian F a)))
    (hbound : ∃ A : Matrix (Fin d) (Fin d) ℤ_[p],
      rationalMatrix p A = (p : ℚ_[p]) ^ s • (rationalMatrix p (jacobian F a))⁻¹) :
    (∃! b : Fin d → ℤ_[p], (∀ i, eval b (perturbSystem p M F H i) = 0) ∧
      (∀ i, (p : ℤ_[p]) ^ (s + 1) | b i - a i)) ∧
    (∀ b : Fin d → ℤ_[p], (∀ i, eval b (perturbSystem p M F H i) = 0) →
      (∀ i, (p : ℤ_[p]) ^ (s + 1) | b i - a i) →
      (∀ i, (p : ℤ_[p]) ^ (M - s) | b i - a i) ∧
      (∃ ε : Fin d → ℤ_[p], (∀ i, (p : ℤ_[p]) ^ (2 * M - 3 * s) | ε i) ∧
        ∀ i, (b i : ℚ_[p]) - (a i : ℚ_[p]) =
          -(p : ℚ_[p]) ^ M * ((rationalMatrix p (jacobian F a))⁻¹).mulVec
            (fun j => (eval a (H j) : ℚ_[p])) i + (ε i : ℚ_[p]))) := by
  obtain ⟨b, hb, hdepth, hball, huniq, herror⟩ := exists_root_motion p s M hM F H a hFa hJ hbound
  constructor
  · exact ⟨b, ⟨hb, hball⟩, fun z hz => huniq z hz.1 hz.2⟩
  · intro z hz hzb
    rw [huniq z hz hzb]
    exact ⟨hdepth, herror⟩
```

Proof reading. The existence theorem constructs a root using the original preconditioner. Its error estimate combines the quadratic Taylor remainder with the perturbation's change under the root displacement, then applies the inverse bound, costing the stated s digits. The unique-existence endpoint transports both the depth and the error formula to every root in the uniqueness ball. It does not assign a fixed linear map to a nonlinear finite displacement. It estimates that displacement by a linear leading term plus a rigorously bounded remainder.

10.5 Parameter and coefficient motion share one forcing term

Now $F(y,t)$ has a square solved block J and parameter block K. Perturb the coefficients by $p^M H$ and prescribe $t' = t + p^M v$. The solved-coordinate leading displacement is

$$y' - y = -p^M J^{-1}(H(a) + Kv) + \varepsilon, \qquad p^{2M-3s} \mid \varepsilon.$$

The extra Kv term is required even when $H = 0$. The source uses the actual evaluated partial derivatives in both blocks.

Contract. The theorem requires the same inverse bound on the solved block, $M > 2s$, an exact initial root, and the stated parameter displacement. Uniqueness is among roots with that exact new parameter in the depth-$s+1$ ball.

Source: `polynomial_regularity/formalization/PolynomialJointMotion.lean`.

Lines 76–105; `Komorebi.PolynomialJointMotion.exists_joint_root_motion`.

```
theorem exists_joint_root_motion (p s M : ℕ) [Fact p.Prime]
    (hM : 2 * s < M) (F H : Fin e → MvPolynomial (Fin (e + k)) ℤ_[p])
    (a : Fin (e + k) → ℤ_[p]) (v : Fin k → ℤ_[p])
    (hFa : ∀ i, eval a (F i) = 0)
    (hJ : IsUnit (rationalMatrix p (solvedJacobian F a)))
    (hbound : ∃ A : Matrix (Fin e) (Fin e) ℤ_[p],
      rationalMatrix p A = (p : ℚ_[p]) ^ s • (rationalMatrix p (solvedJacobian F a))⁻¹) :

      (∀ i, (p : ℤ_[p]) ^ (M - s) | b i - a i) ∧
      (∀ i, (p : ℤ_[p]) ^ (s + 1) | b i - a i) ∧
      (∀ z : Fin (e + k) → ℤ_[p],
        (∀ i, eval z (F i) + (p : ℤ_[p]) ^ M * eval z (H i) = 0) →
        freePart z = freePart a + (p : ℤ_[p]) ^ M • v →
        (∀ i, (p : ℤ_[p]) ^ (s + 1) | z i - a i) → z = b) ∧
      (∃ ε : Fin e → ℤ_[p], (∀ i, (p : ℤ_[p]) ^ (2 * M - 3 * s) | ε i) ∧
        ∀ i, ((solvedPart b i : ℤ_[p]) : ℚ_[p]) - ((solvedPart a i : ℤ_[p]) : ℚ_[p]) =
          -(p : ℚ_[p]) ^ M * ((rationalMatrix p (solvedJacobian F a))⁻¹).mulVec
            (fun j => ((eval a (H j) + (parameterJacobian F a).mulVec v j : ℤ_[p]) : ℚ_[p])) i +
          (ε i : ℚ_[p])) := by
  obtain ⟨A, hA⟩ := hbound
  obtain ⟨hAJ, hJA⟩ := certificate_of_integral_inverse p s (solvedJacobian F a) A hJ hA
  obtain ⟨b, hb, ht, hdepth, hball, huniq, herror⟩ :=
    exists_joint_root_certificate p s M hM F H a v A hAJ hJA hFa
  obtain ⟨ε, hε, hformula⟩ := PolynomialMotionRational.exists_rational_error
    p s M (2 * M - 3 * s) (by omega) (solvedJacobian F a) A hA
    (solvedPart a) (solvedPart b)
    ((fun j => eval a (H j)) + (parameterJacobian F a).mulVec v) herror
  exact ⟨b, hb, ht, hdepth, hball, huniq, ε, hε, hformula⟩
```

Proof reading. The source converts the solved inverse bound into a certificate, constructs the augmented root, and obtains an integral error equation. `exists_rational_error` then divides the certificate relation in the fraction field and identifies the first-order term. The coordinate split ensures the final error concerns solved coordinates. Free coordinates already have their exact prescribed displacement.

The retained controls reject omitting the parameter forcing term, reversing its sign, and demanding an extra uniform error digit. They use explicit boundary systems, so those exclusions are mathematical constraints rather than stylistic choices. The resulting theorem is local quantitative deformation, not a global branch-selection theorem.

11 Actual derivatives and analytic local graphs

11.1 The polynomial Jacobian becomes a strict derivative

The earlier integer Taylor lemma proves divisibility. Analytic regularity needs a different bridge: actual polynomial evaluation must have the strict Fréchet derivative represented by the evaluated formal Jacobian. The source proves the scalar derivative by polynomial induction and assembles finite coordinates.

Contract. $\mathbb{K}$ is a complete nontrivially normed field. F is a vector of actual multivariate polynomials over $\mathbb{K}$. The strict derivative of evaluation at a is the continuous linear map represented by the actual Jacobian.

Source: `polynomial_regularity/formalization/PolynomialAnalyticEvaluation.lean`.

Lines 76–85; `Komorebi.PolynomialAnalyticEvaluation.hasStrictFDerivAt_evalSystem`.

```
theorem hasStrictFDerivAt_evalSystem (F : Fin m → MvPolynomial (Fin n) 𝕜)
    (a : Fin n → 𝕜) :
    HasStrictFDerivAt (evalSystem F) (matrixCLM (PolynomialWeightedInverse.jacobian F a)) a := by
  have h := hasStrictFDerivAt_pi.mpr (fun i => hasStrictFDerivAt_eval (F i) a)
  have hder : ContinuousLinearMap.pi (fun i => polynomialDeriv (F i) a) =
      matrixCLM (PolynomialWeightedInverse.jacobian F a) := by
    ext v i
    simp [PolynomialWeightedInverse.jacobian, Matrix.mulVec, dotProduct]
  rw [← hder]
  convert! h using 1
```

Proof reading. Each scalar polynomial has its proved derivative. `hasStrictFDerivAt_pi` assembles those coordinate derivatives. Extensionality of continuous linear maps compares their action on every vector and coordinate. Unfolding the matrix action yields the same finite dot product as the formal partial derivatives. The final conversion identifies the evaluated system with this coordinate assembly.

Analyticity of actual polynomial evaluation is supplied through the pinned Mathlib multivariate-polynomial theorem and finite coordinate assembly. It is not a hypothesis about a proposed solution map. The development also proves the derivative block identities for the actual augmented polynomial system. A user cannot supply an unrelated matrix and call it the Jacobian.

11.2 The strict local inverse is the analytic inverse

Contract. In the inverse helper, $\mathbb{K}$ is nontrivially normed; E, F are normed spaces over it; E is complete; and $i : E \simeq_L F$ is a continuous linear equivalence. The function is analytic at a and has strict derivative i there.

Source: `polynomial_regularity/formalization/PolynomialAnalyticInverse.lean`.

Lines 28–32; `Komorebi.PolynomialAnalyticInverse.analyticAt_inverse`.

```
theorem analyticAt_inverse (ha : AnalyticAt 𝕜 f a)
    (hd : HasStrictFDerivAt f (i : E →L[𝕜] F) a) :
    AnalyticAt 𝕜 (hd.localInverse f i a) (f a) := by
  exact (hd.toOpenPartialHomeomorph f).analyticAt_symm'
    hd.mem_toOpenPartialHomeomorph_source ha hd.hasFDerivAt.fderiv
```

Proof reading. The strict derivative's local inverse is the inverse of its associated open partial homeomorphism. The Mathlib analytic inverse theorem applies to that same inverse, using the derivative identity. The proof does not construct one analytic inverse and separately assume it agrees with the root-solving inverse. The two are linked by the explicit partial homeomorphism.

These helper hypotheses are slightly different from the polynomial endpoint's ambient hypotheses. In particular, the helper only declares completeness of its source space E, while the endpoint gets it from the complete field and finite-dimensional coordinates. Reading the full variable context prevents a short excerpt from concealing these assumptions.

11.3 The augmented derivative exposes the sign

For the map $\Phi(y,t) = (F(y,t),t)$, the actual derivative at a and its inverse are

$$D\Phi(a) = \begin{pmatrix} J & K \\ 0 & I \end{pmatrix}, \qquad D\Phi(a)^{-1} = \begin{pmatrix} J^{-1} & -J^{-1}K \\ 0 & I \end{pmatrix}.$$

The source constructs the continuous linear equivalence from these matrices and verifies both products. Inserting a pure parameter displacement $(0,v)$ into the inverse yields solved displacement $-J^{-1}Kv$.

Contract. J is a square invertible matrix over the normed field and K has the specified rectangular shape. The explicit augmented equivalence's inverse, restricted to parameter input and solved output, equals the continuous linear map of $-J^{-1}K$.

Source: `polynomial_regularity/formalization/PolynomialAnalyticBlocks.lean`.

Lines 59–66; `Komorebi.PolynomialAnalyticBlocks.inverse_solved_zero`.

```
theorem inverse_solved_zero (J : Matrix (Fin e) (Fin e) 𝕜)
    (K : Matrix (Fin e) (Fin k) 𝕜) (hJ : IsUnit J) (v : Fin k → 𝕜) :
    solvedPart ((upperEquiv J K hJ).symm (join (0 : Fin e → 𝕜) v)) =
      matrixCLM (-(J⁻¹ * K)) v := by
  rw [upperEquiv_symm_apply]
  simp only [blockCertificate, upperBlock_mulVec_join, Matrix.mulVec_zero,
    zero_add, solvedPart_join]
  rfl
```

Proof reading. The proof unfolds the actual inverse equivalence and its certificate, evaluates the upper block on the joined vector, and removes the zero solved input. The negative sign is therefore an algebraic consequence of the inverse block identities. The dedicated derivative-sign negative control checks a concrete contrary statement.

11.4 The graph is exact in a product neighborhood

Contract. $\mathbb{K}$ is a complete nontrivially normed field; $F \in \mathbb{K}[Y,T]^e$ is an actual polynomial system with e solved and k parameter coordinates; $F(a) = 0$; and the solved Jacobian J is invertible. The theorem constructs open neighborhoods U, V, an analytic solution ψ, and exact equivalence $F(y,t) = 0 \iff y = \psi(t)$ for $t \in U, y \in V$.

    exact inverse_solved_zero J K hJ v
  simpa only [heq] using hder
```

Proof reading. The proof names the actual solved and parameter blocks J, K, constructs their upper-block continuous equivalence, and identifies the augmented polynomial map with $z \mapsto (F(z), \pi_T z)$.

Actual polynomial analyticity and the strict derivative bridge provide the inputs to the analytic graph helper. The helper takes a local inverse g and defines $\psi(t) = \pi_Y g(0,t)$. The final linear-map identity restricts g's inverse derivative to obtain $-J^{-1}K$.

The graph helper shrinks the parameter neighborhood so that four requirements hold together: the inverse identities, analyticity, the requested product neighborhood, and $\psi(U) \subseteq V$. This shrinking is part of the proof. It is not enough to know an inverse exists at the base point and then claim every point in an arbitrary ball lies in its domain.

The function ψ is defined on the ambient parameter space, but the root and regularity conclusions are restricted to U. Uniqueness is among $y \in V$. Analyticity on the neighborhood implies differentiability there. The displayed strict derivative formula is at the specified base point. The open-set selection theorem later obtains the analogous derivative at every point by applying the local theorem repeatedly.

11.5 A supplied continuous root selection acquires regularity

Contract. Keep the same field and solved-block nonsingularity. A supplied map g is continuous at the base parameter, has the correct base value, and solves the exact polynomial equation on a neighborhood. No derivative or analyticity of g is assumed.

Source: `polynomial_regularity/formalization/PolynomialAnalyticSelection.lean`.

Lines 39–56; `Komorebi.PolynomialAnalyticSelection.continuous_selection_regularity`.

```
theorem continuous_selection_regularity
    (F : Fin e → MvPolynomial (Fin (e + k)) 𝕜)

  exact ⟨(hψ (freePart a) ht).congr heq.symm, hdψ.congr_of_eventuallyEq heq.symm⟩
```

Proof reading. The root equation at the base point follows from the eventual neighborhood equation and the given base value. The analytic graph theorem constructs ψ. Continuity places $g(t)$ in V for all sufficiently close t, while openness places t in U. The exact graph equivalence forces $g = \psi$ as germs. Analyticity and the strict derivative transfer through eventual equality.

For a continuous exact root selection on an open set, the source requires an invertible solved Jacobian at every point of that set. It then proves analyticity and the actual implicit derivative at every point. A single nonsingular point does not justify regularity of a branch through later singular points. Arbitrary global branch choices are outside this germ comparison.

11.6 Integral coefficients are evaluated in the fraction field

Contract. For any prime p, the coefficients and base point may lie in $\mathbb{Z}_p$. Only the solved Jacobian after inclusion in $\mathbb{Q}_p$ must be invertible. The resulting neighborhoods and analytic map live in the ambient $\mathbb{Q}_p$ vector spaces.

Proof reading. The source proves that evaluation, formal partial derivatives, and both Jacobian blocks commute with the coefficient inclusion. It applies the actual polynomial implicit theorem to the included system and point, then rewrites its equation and derivative back in terms of the original integral coefficients. Invertibility modulo p is not required. The included solved Jacobian may therefore be singular modulo p while remaining invertible over $\mathbb{Q}_p$.

This is an ambient-field analytic theorem. It does not make $\mathbb{Z}_p$ a vector space over $\mathbb{Q}_p$, assert that every nearby analytic value is integral, or supply a new explicit integral radius. The earlier weighted and residue-ball theorems retain their own quantitative domains. Nor does it prove a branch through a point whose solved Jacobian is singular over the fraction field. General singular persistence and global compatibility remain separate research problems.

12 Formal evidence and its limits

12.2 The negative controls mark mathematical boundaries

Retained regularity control	Boundary being guarded
`InvalidGlobalUniqueness`	Local root uniqueness cannot be extended to all roots.
`InvalidRectangularUniqueness`	A surjective rectangular digit map can have a nontrivial kernel.
`InvalidPerturbationExtraPrecision`	A perturbation does not supply a free additional congruence digit.
`InvalidWeightedBoundary`	The weighted residual threshold requires $r > 2s$.
`InvalidWeightedExtraPrecision`	The inverse-bound loss in retained precision can be sharp.
`InvalidMotionExtraErrorDigit`	The first-order remainder exponent cannot be uniformly increased.
`InvalidPrescribedParameter`	A fixed parameter must satisfy its actual digit equation.
`InvalidPrescribedFullJacobian`	Full Jacobian surjectivity does not replace solved-block surjectivity.
`InvalidPrescribedRectangularUniqueness`	Prescribed parameters do not eliminate a solved-block kernel.
`InvalidJointMissingParameterTerm`	Joint motion needs the actual Kv forcing term.

Retained regularity control	Boundary being guarded
`InvalidJointParameterSign`	Solved motion has the negative inverse-Jacobian sign.
`InvalidRegularityDerivativeSign`	The analytic implicit derivative is $-J^{-1}K$.

The controls compile attempted statements using positive examples that contradict the strengthened conclusions. Their expected compiler rejection is recorded evidence that the false theorem application does not type-check in the inherited run. The mathematical explanation of the relevant examples appears in the manuscript and source control modules. A failed attempt alone does not prove the negation of an arbitrary unformalized conjecture.

12.4 Remaining questions

Chapter IX closes the recorded arithmetic, smooth finite lifting, prescribed towers, quantitative deformation, and local analytic regularity results under their stated hypotheses. It retains open unrestricted native presentation invariance, completed/global compatibility and descent, general singular persistence with higher obstructions, and other specified arithmetic extensions. The analytic inverse theorem does not close those programs.

The original mathematical text and the continuation sources have separate provenance. Inclusion in this collection does not assign a blanket formal certificate to every argument. The Bernoulli specialization has a classical derivation and no matched dedicated Lean bridge.

13 Current manuscript-to-guide navigation

This table resolves all 62 inherited statement entries against the current 232-page monograph. The paper column gives physical PDF pages, counting the cover. The guide column uses printed pages. The 202 exact formal source links are retained in the paired JSON without changing their source hashes. A separate classical example follows the indexed entries. Current monograph SHA-256: `1975d95d124cdb303452950c272917c2e3fc20c19fdc882ad39b8f9744d328ca`.

The proof chain deliberately retains its interfaces: integer Taylor identities feed digit obstructions and towers; contraction and inverse certificates feed quantitative weighted lifting; actual polynomial strict derivatives and augmented inverse blocks feed the analytic graph. A direct import is a dependency relation; it is not by itself a theorem correspondence or a fresh compiler check.

16 Complete named-source catalog

This catalog contains all 1,876 declaration rows under 199 canonical source files. The accompanying CSV retains exact-copy locations, roles, file identities and axiom closures. A theorem command, a control, a construction and a source file are different objects. A new name alone does not establish a new mathematical result.

Return to Chapter X

Abstract

This guide explains the source contracts behind Chapter X rather than treating its terminal signature as a stand-in for the mathematics. It provides a concordance of the twenty source records, follows the two independent construction branches, and distinguishes arithmetic occurrence, finite trace recovery, carrier presentations, local comparison data, and nonzero occupancy. Four complete production modules are printed from preserved source. Their verification scope is stated separately.

1 Formal verification and scope

The recorded compiler checks cover 122 project and support modules, including the 97-module terminal closure. Two clean builds agreed on 392 artifacts. The matching Lean toolchain and all nine dependency identities were checked. External Mathlib caches were reused. This is not a cold dependency rebuild.

Owned declarations and explicit targets. The fresh audit checked all 2,846 declarations owned by the 122 selected modules, including 2,127 theorems, 444 private declarations, and generated declarations. All 45 explicit target contracts resolved with the required kind and owner. Their complete elaborated types are retained. The union of transitive axioms was exactly `propext`, `Classical.choice`, and `Quot.sound`. No forbidden dependency was found. The source records give the checking procedure and its limits. The 18 compiler fixtures and 64 unit tests check tooling and are separate from these production counts.

Correspondence requires mathematical reading. The twenty-row register is a reading concordance. Its three incorrect source routes have been corrected to the actual residual-obstruction, reconstruction, and empty-level declarations. The independent bounded source review checked the amended terminal composition and finite-copy carrier closure under their explicit inputs. It is not a new proof audit of every historical theorem. Classical Inputs 3.1 and 4.1 and the conjectures remain outside the twenty-row concordance. Compiler acceptance and name resolution alone do not prove manuscript equivalence.

Finite checks have separate bounds. The current replay passed the original 28 companion tests and 13 reader regression methods, including 3,123 canonical residue towers through depth four over bases 2, 3, 5 and 7. The visual suite passed 263 positive assertions and rejected 14 false controls. Six further finite suites retain their actual bounds, seeds and logs separately. These counts are not combined into a theorem count.

The mathematical boundary is unchanged. The transported target family and recovered carrier summand are independent existential conclusions. Their identification requires another comparison. The literal constructed arithmetic separator is over `GQ`. Local comparisons, carrier presentations and source-family data remain inputs. Zero multiplicities are admitted. Nonzero occupancy needs its own premise. Universal occupancy and natural finite seed rank remain conjectures. The later stronger residual-system attempt remains separately preserved and unpromoted.

2 How to read the formal evidence

Chapter X has a finite and formal core, a substantial arithmetic development, and a terminal conditional assembly. These are not three names for one assertion. The source register below gives the twenty numbered proof records in the main manuscript. The checked endpoint concerns their recorded amended scope. Later arithmetic prose can still require hypotheses which an application has not supplied.

A Lean declaration proves its type, including implicit parameters and typeclass assumptions. A short proof can therefore depend on a long contract. Here the terminal proof is only six lines: it constructs a conjunction and invokes two previous theorems. The mathematical content is distributed across those theorems and their dependencies. Reading only the final six lines would miss the source family, all-depth naturality, inverse-limit closure, carrier presentations, and constituent local comparisons.

2.1 Three different records

Record	Interpretation
Base scalar/Mellin	Base 17/20: Claims 9.1, 9.2 and 11.1 are partial in that contract.
Conditional assembly	Recorded 20/20 under an explicitly amended contract. The target family and carrier summand are independent conclusions.
Stronger residual contract	19/20 under a stronger contract with an unproved terminal claim. This does not invalidate the conditional assembly.

The records distinguish the accepted conditional theorem from the incomplete attempt at a stronger conclusion. The latter neither replaces nor invalidates the former.

2.2 What each kind of check can establish

An exact Python calculation verifies the displayed finite instance or enumerated range. A source hash verifies identity of bytes. A successful typeset build verifies that the document can be generated. A saved compiler log reports a past compilation. None of these is a fresh proof of every theorem in the collection. A transitive axiom report also has a specific declaration set and environment. Its scope is not enlarged by binding it into a longer monograph.

3 The twenty source records

The numbered entries below are the main manuscript's twenty theorem, proposition, and corollary records. Classical Inputs 3.1 and 4.1 are not counted as new proof records. Definitions, examples, numerical certificates, and the conjecture that the seed rank is finite are also excluded from this count.

This is a reading concordance, not a claim that twenty lines of a table replace twenty theorem-to-source audits. The earlier seventeen entries retain their hypotheses. The final three arithmetic entries must be read through the amended source contract explained in Sections 7–11. Links target named destinations in the companion monograph. Keep the three PDFs in the same directory for relative file links to resolve.

Record	Statement and source route	Hypothesis to retain
2.1	Residual partition. `Residual`	A supplied, single-valued reduction map.
2.2	No crossing under positive-depth perturbation. `Residual`, `SeedConsequences`	Root-preserving operations. The infinite statement assumes convergence.
2.3	Zeroth-order obstruction. `Residual.zeroth_order_obstruction`	Different roots cannot be reached by genuine positive-depth operations.
3.2	Formal inverse-limit reconstruction. `Reconstruction.represented_local_algebra_reconstruction`	Represented complete local problems with compatible finite maps.
3.3	Finite-branch compactness. `Compactness`, `RepresentationForests`	Finite nonempty levels and the stated total reduction maps.
3.4	Smooth formal branch count. `SmoothMaps`, `IntegralCharts`	An actual power-series chart and coefficient-preserving local maps.
4.2	Cohomology packet decomposition. `ComplexCohomology`, `PacketCohomology`	A finite complete orthogonal family of chain projectors.
5.3	Weighted smooth-chart count. `Counting`, `FormalCharts`	Independent coordinates with the stated valuation lower bounds.
6.2	Smooth seed zeta function. `Zeta`, `SmoothModels`	The smooth-chart count, as an infinite formal power series.
6.3	Weighted seed zeta function. `Zeta`	The stated ordered positive weights, with finite initial levels separated.
6.4	Singular power seed. `Singular`, `SingularZeta`	The scalar equation x to the e equals zero at finite precision.
6.6	Fractional singular dimension. `BranchingDimension`, `Singular`	A finite-count growth exponent, not the dimension of a limit space.
7.3	Directed minimum-seed theorem. `DirectedSeeds`	A finite supplied graph. Arithmetic admissibility of edges is separate.
8.2	Adelic finite-depth completion. `ClassCommonSpine`, `SystemCompletion`	Common data, finite-depth nonemptiness, and inverse-limit-closed conditions.
8.3	Residual companion obstruction. `SystemCompletion.system_empty_level_obstruction`	An empty required finite level rules out the specified realization.
9.1	Finite Frobenius separation. `Claim91ConstructedClosure`	Later constructed rational-base separator, with its literal compatible-family inputs.
9.2	Compatible-carrier summand completion. `StrictCompatibleCarrierCompletion`	Explicit copy presentations, natural multiplicities within capacity, and supplied local data.

Record	Statement and source route	Hypothesis to retain
10.1	Exact finite occupancy trace. `SpectralProjectors`, `JointOccupancy`	Commuting split semisimple operators. The positive-trace interpretation uses characteristic zero.
11.1	Residual-system completion criterion. `ConditionalOccupiedSystemCompletion`	The later amended two-conjunct contract, not universal residual existence.
11.2	Exact location of the remaining existence problem. `SpineExistenceCriterion`, `RequiredPacketOccupancy`	All required finite levels and all supplied packet occupancy premises.

The monograph retains the general-base mathematical discussion. In contrast, the printed constructed arithmetic separator and the terminal assembly use `GQ`, the rational absolute Galois group. That literal base is part of the formal statement. An arbitrary-number-field version requires its own attachment and proof, not a change in a heading.

4 Residual roots and reconstruction

The fiber decomposition begins with a function, the reduction map. For an object x in a coefficient algebra A, its residual root is $\mathrm{red}_A(x)$. Distinct fibers are disjoint because a function has one value at each input. No topological or representation-theoretic theorem is needed for that partition.

The no-crossing theorem adds a hypothesis about the allowed operation. A positive-depth correction is trivial after residual reduction. A finite sequence of such corrections therefore stays in one fiber. An infinite sequence needs a convergence assumption. The sequence $0, 3, 0, 3, \ldots$ has one residue modulo three but does not converge modulo nine. Residual invariance is weaker than being Cauchy.

4.1 A point in an inverse limit is a coherent family

For a represented complete deformation problem, compatible finite maps determine one map into the inverse-limit coefficient ring. The argument does not assert that every finite object can be extended. Nor does it produce a map when the finite levels are empty. Reconstruction and existence remain distinct.

The finite-branch argument supplies existence when all levels are finite and nonempty and the transition maps are the stated reductions. Surjectivity of every transition map is unnecessary. Some nodes may die. The surviving branch is obtained from nodes with descendants at arbitrarily large depths. Finiteness prevents indefinitely moving the root to a new unrelated component.

Plate X.9 displays the infinite-level countermodel $X_m = \{n \geq m\}$ with inclusion maps. Each level is nonempty, but a compatible family would have to be one integer n lying in every X_m. No such integer exists. Its infinite levels violate the compactness hypotheses. This is a countermodel to dropping finiteness, not to the finite-level theorem.

4.2 The corrected digit formula

For compatible canonical residues $0 \leq x_m < p^m$, the digit in position $m-1$ is

$$a_{m-1} = \left\lfloor \frac{x_m}{p^{m-1}} \right\rfloor \pmod{p}.$$

Set $x_0 = 0$. Compatibility also makes

$$a_{m-1} = \frac{x_m - x_{m-1}}{p^{m-1}} \in \{0, \ldots, p-1\}.$$

The earlier algorithm display omitted the floor. The executable implementation already used integer division. For the base-five residues $4, 19$, the new digit is 3. Dividing 19 by 5 in the rationals does not recover a digit. The new regression checks compare the displayed formulas with the inherited executable on exhaustive bounded towers, including noncanonical integer representatives for the floor formula.

5 Counting finite points without inventing limit points

In a smooth chart $\mathcal{O}[[t_1, \dots, t_d]]$, local maps into $\mathcal{O}/\varpi^m$ send each parameter into the maximal ideal. There are q^{m-1} possibilities for each independent coordinate, giving $q^{d(m-1)}$ maps. The word independent is justified by the power-series presentation, not by the appearance of a grid in a figure.

Weighted coordinates with $t_i \in \varpi^{w_i}\mathcal{O}$ have $\max(m - w_i, 0)$ free residue digits. Thus

$$N_{\mathbf{w}}(m) = q^{\sum_i \max(m-w_i,0)}.$$

For weights $(1, 2, 4)$ over $\mathbb{Z}_2$, the counts begin $1, 2, 8, 32, 256, 2048$. The coordinate of weight four is not nontrivial at depth four. It first has a free digit at depth five. The weight and first visible depth are different quantities.

5.1 The singular count is not a count of infinite branches

For $x^e = 0$ modulo ϖ^m, the condition is $e\, v_{\varpi}(x) \geq m$. Its finite cardinality is $q^{m-\lceil m/e \rceil}$. Splitting $m = ek + r$, $1 \leq r \leq e$, gives

$$Z_e(T) = \frac{\sum_{r=1}^{e} q^{r-1} T^r}{1 - q^{e-1} T^e}.$$

This is an identity of formal power series. Its growth exponent $1 - 1/e$ measures the finite thickenings. It does not imply that the complete solution space has a fractional geometric dimension. In the integral domain $\mathcal{O}$, the only complete root of $x^e = 0$ is zero. Equivalently, the reduction at depth m of a root at depth em is zero. Every coherent infinite branch is therefore the zero branch.

The smooth, weighted, and singular cases teach different tests. A complete chart can have many genuine branches. A weighted chart delays their finite visibility. A singular thickening can have many finite roots and only one complete branch. The generating series must always be interpreted for the object it actually counts.

6 Cohomology packets and directed transport

A degreewise idempotent is not automatically a map of complexes. The required identity is $d_r P_j^r = P_j^{r+1} d_r$. Together with orthogonality and a sum equal to the identity, this makes the images into subcomplexes. The induced maps on cycles and boundaries then descend to cohomology. Their inverse identities give

$$H^r(C^\bullet) \simeq \bigoplus_j H^r(P_j C^\bullet).$$

The comparison with tangent or obstruction spaces of a particular deformation problem is an additional identification. The packet theorem itself is a theorem about a complex with supplied chain projectors.

Plates X.10 and X.11 use a complex over $\mathbb{F}_5$ with dimensions $(2, 4, 2)$. The valid packet family gives cohomology dimensions $(1, 2, 1)$. A modified idempotent deletes the image of a retained source vector and fails the chain-map identity. All its individual matrices remain idempotent. The missing condition is compatibility with the differential, not idempotence.

6.1 A transport graph is data before it is an optimization problem

For a finite directed graph, contract strongly connected components. The resulting graph is acyclic. Every generating seed set must meet each source component, since no other component can reach into that source. Conversely, one vertex from every source reaches all components. This proves the directed minimum-seed formula.

The theorem optimizes a supplied graph. An arithmetic twist, induction, or coefficient change is an edge only after its admissibility has been established. Adding an unjustified arrow can lower the computed seed rank without proving anything about the original arithmetic problem. Likewise, a finite graph theorem does not settle the conjectural finite seed rank of an unrestricted arithmetic transport category.

6.2 Transport must respect every reduction square

For roots of $x^2 + 1$ modulo powers of five, negation preserves the equation and commutes with every reduction. Translation by one maps the root two to the root three modulo five, but maps three to four, which is not a root. One successful pair of endpoints does not define a natural operation on the whole tower. The formal interface in the next section expresses exactly this distinction.

7 Horizontal completion, hypothesis by hypothesis

The module `HorizontalTransportCompletion` works with actual change-of-basis classes. Its structure `AdmissibleClassTransport` has three fields: a map at every precision, preservation of allowed classes, and compatibility with reduction. Those fields are the data of a map of inverse towers.

A completed source representation ρ first gives a coherent branch of its finite classes. Applying the transport at each depth gives a coherent target branch. The predecessor reconstruction theorem then supplies an actual target representation. This is stronger than mapping one residual root, but it is still conditional on the existence of the completed source representation.

7.1 The local profile is not hidden in the word reconstruction

`TransportedAlong` records, for every depth, equality between the reduced target class and the transported source class. An arbitrary semantic property of the complete representation does not follow from that equality alone. The theorem therefore accepts `InverseLimitClosed` for the selected target profile and finite-level conditions. Applying the closure theorem to the reconstructed target establishes that profile.

For example, nontriviality is not a closed condition under the relevant limit. The matrices

$$\rho_n(g) = \begin{pmatrix} 1 & 3^n g \\ 0 & 1 \end{pmatrix}$$

are nontrivial representations of the additive integers, while they converge pointwise to the trivial representation in the three-adic topology. A proof of nontriviality for every approximation is not a proof of nontriviality for its limit. This example does not decide the closedness of any particular arithmetic local condition. That condition needs its own theorem.

7.2 What changes when coefficient places are indexed

The indexed theorem takes a source member at every λ. It first proves an existence statement at each place, then uses choice to select a family of target members. The source code explicitly verifies three outputs at every place: finite-depth admissibility, the relation `TransportedAlong`, and membership in the target profile.

This is an indexed family statement. Any interpretation as a compatible arithmetic system depends on the shared data encoded by the conditions and profiles. Merely placing unrelated local objects in one function indexed by λ is not a new compatibility theorem. The abstract horizontal module is general in the source group, but the terminal assembly printed here specializes that group to `GQ`.

8 From arithmetic occurrence to a finite separator

The constructed Claim 9.1 module has two declarations. The first provides its `ExistentialArithmeticC` overage proposition by calling the constructed Chebotarev bridge. The second applies the arithmetic system-separation theorem to that proposition. In this later source there is no free external coverage parameter in the final separator signature. The scalar/Mellin interface retains that parameter. Both sources remain in the archive.

8.1 What the separator accepts

The family consists of finite-dimensional irreducible representations, compatible character values in a common field, continuous characters at each realization, and pairwise nonisomorphism in the stated memberwise sense. At each coefficient place the bad-prime set is finite. The caller selects a distinguished place and may forbid an additional finite set of rational primes.

The result selects distinct allowed rational primes. The common sample matrix has nonzero determinant, and that remains true after each coefficient-field embedding. Matrix entries identify with the representation characters wherever the required good-prime condition holds. The terminal wrapper then converts this matrix identity into the literal trace determinant needed by the carrier theorem.

Distinct primes alone would not suffice. Samples could repeat one character row and leave the matrix singular. Nonisomorphism, arithmetic occurrence, and the finite-dimensional separation argument do different work.

8.2 The finite character-table model

With columns trivial, sign, and standard, use

$$C = \begin{pmatrix} 1 & 1 & 2 \\ 1 & -1 & 0 \\ 1 & 1 & -1 \end{pmatrix}, \qquad \det C = 6, \qquad C \begin{pmatrix} 2 \\ 0 \\ 1 \end{pmatrix} = \begin{pmatrix} 4 \\ 2 \\ 1 \end{pmatrix}.$$

The table explains multiplicity recovery after separating samples exist. It does not produce rational primes with prescribed Frobenius behavior. The arithmetic occurrence construction is represented by the preserved source and its inherited verification record, not by this finite example.

8.3 Exact recovery can still lose finite precision

Over characteristic zero, C is invertible. Modulo eight, $\delta m = (4, 4, 0)$ is nonzero but $C\delta m = (8, 0, 8)$ vanishes. The denominator valuation consumes one binary digit. Traces modulo sixteen distinguish this particular ambiguity. The example separates invertibility over a field from invertibility over a residue ring. Plate X.17 gives the complete small model.

9 Carrier recovery is a construction inside supplied data

Let the supplied carrier be equivariantly presented as $\bigoplus_i W_i^{\oplus c_i}$, and let the chosen multiplicities satisfy $m_i \le c_i$. The copy inclusion and projection give maps j and r with $r \circ j = \mathrm{id}$. Transporting these through the carrier presentation produces an actual split summand. An arbitrary vector of traces does not provide that presentation.

The initial subrepresentation is also supplied with an equivariant presentation by the same selected copies. The nonsingular sample matrix proves that no other natural multiplicity vector has those sample traces. Thus the theorem constructs splittings and proves uniqueness within the declared constituent family. It does not discover an unknown irreducible decomposition from raw observations.

9.1 Three tests after solving a linear equation

For capacities $(2, 1, 1)$, the vector $(2, 0, 1)$ is admissible. The trace vector $(1, 0, 0)$ instead gives $(1/6, 1/6, 1/3)$, which is not integral. The vector $(-1, 1, 1)$ is integral but negative. The vector $(3, 0, 1)$ exceeds capacity. Each has a perfectly well-defined rational trace vector under the same matrix. A nonsingular system alone does not turn its solution into a representation.

9.2 What happens to local data

The source constructs finite copies of supplied local packets. Characteristic polynomials multiply with multiplicities. Relevant dimensions and traces add. The supplied period comparisons similarly produce the selected finite-copy comparison and weight-multiplicity formulas.

These identities do not attach Weil–Deligne or period data to an arbitrary new representation. The data and comparisons are input. An extra semantic condition is handled separately by `FiniteCopyClosed`. The terminal `CarrierRecoveryAt` packages specific polynomial, local, and period identities. It does not universally quantify over every possible local predicate. The separate `selected_local_condition` theorem applies only after its finite-copy-closure premise has been proved.

A fixed nontrivial determinant character illustrates the distinction. Two one-dimensional constituents can each have determinant χ, while their direct sum has determinant χ^2, not χ. A determinant target must be combined according to its actual product law. The word local does not make a condition stable under arbitrary sums.

10 Occupancy and the missing nonzero premise

The identity $\mathrm{Tr}(P) = \mathrm{rank}(P)$ for a projector over a characteristic-zero field is interpreted through the natural-number rank cast into that field. Positivity means positivity of this integer, not an order on an arbitrary coefficient field. In positive characteristic, a nonzero projector can have field-valued trace zero. The rank remains the correct nonemptiness test.

For commuting split semisimple operators, products of their exact spectral projectors detect joint eigenspaces. Pairwise occupancy need not imply joint occupancy. Plate X.18 uses six binary labels for which each pair of the target conditions $(0, 1, 1)$ is witnessed, while the complete triple is absent. The product projector is zero although all pairwise tests pass.

10.1 Why the terminal assembly permits an empty selection

The multiplicities are natural numbers. The vector $m_i = 0$ satisfies $m_i \le c_i$ for every carrier. Its selected copy space is zero, its splitting is valid, and its polynomial products are empty products with value one. All of this is consistent with the formal theorem.

To infer a nonzero summand, an application needs an index i with $m_i > 0$ and a nonzero constituent W_i. Under the finite-dimensional field assumptions,

$$\dim\Big(\bigoplus_i W_i^{\oplus m_i}\Big) = \sum_i m_i \dim W_i > 0$$

then gives the desired conclusion. Dropping that premise would strengthen the theorem to a false statement.

The indexed required-packet criterion is a different statement. It requires a nonzero vector in every supplied required packet. A finite sample of packet indices need not test them all. It also does not produce one common vector belonging to several unrelated carriers. Quantifiers and carrier types must remain visible in the application.

11 The final conjunction and its exact logical strength

Write $A(\sigma)$ for the transported-family conclusion and $B(S)$ for carrier recovery. The assembly has the form

$$(\exists \sigma\ A(\sigma))\ \wedge\ (\exists S\ B(S)).$$

It does not assert an isomorphism between the two witnesses. In a finite logical model, A may hold only at zero and B only at one. Both existential statements are true, but no object satisfies both. This elementary countermodel explains why conjoining proofs cannot create a missing comparison.

In the actual source, the separation is stronger than different names: the transported family is represented by matrices over coefficient rings, whereas carrier recovery is formulated through constituents and presentations over coefficient fields. A comparison may need scalar extension, an equivariant isomorphism, and compatibility with the local structures. There is no canonical identification merely because both outputs are called a system or a packet.

11.1 Read the six proof lines

The terminal declaration first uses `constructor`. The left branch calls `exists_transported_system_of_inverseLimitClosed`. The right branch calls `carrier_recovery_from_arithmetic_separator`. The latter obtains a trace separator and invokes the strict compatible-carrier theorem. The dependency pattern is acyclic and the two branches share only the parameters they actually use.

The carrier statement is at an arbitrary distinguished coefficient place. Repeating the theorem at all places requires the corresponding carrier and initial-subrepresentation presentations there. Choice can select witnesses once those pointwise existence statements have been proved. It cannot fill a place at which their hypotheses are unavailable.

11.2 A practical application contract

An application should first identify its complete source members and the actual finite-level transports. It must then prove the target profile’s closure and supply the constituent family, carrier presentations, and compatible sample data. Only after applying the two construction branches should it attempt any desired identification or nonzero conclusion. This order keeps construction, comparison, and occupancy separate rather than using one as an unstated substitute for another.

14 The complete terminal module

# Conditional occupied-system completion

This is the final assembly theorem for Paper X.  It keeps the two conclusions
of the manuscript separate:

* vertical/horizontal completion constructs a simultaneous target family with
  the declared inverse-limit-closed profile;
* arithmetic Frobenius separation and compatible-carrier closure recover the
  declared constituent packet in the known carrier.

No residual companion, carrier, or local comparison is manufactured by this
assembly theorem.  Those are exactly the explicit hypotheses of the conditional
source statement.

Paper X: horizontal transport completion block.

This formalizes the finite-depth content of an admissible residual transport:
a map on representation classes at every precision, preservation of the selected
admissible conditions, and naturality with respect to coefficient reduction.

The main theorem proves that such a transport sends a completed source branch
to a compatible target branch and, over an adically complete coefficient ring
with finite coefficient quotients, reconstructs an actual target
representation realizing that transported branch.  No arithmetic transport is
asserted unless supplied through the `allowed` predicates and the transport
fields below.

# Compatible-carrier summand completion

This is the source-faithful closure theorem for Paper X Claim 9.2.  The
constituent representations, their strict local Weil packets, and their genuine
semilinear Tate comparisons are inputs.  The selected multiplicities are then
used at every coefficient realization.  The theorem constructs the actual split
summand and proves closure of all local data under those finite copies.

It does not construct a compatible carrier or prove that an arbitrary p-adic
representation is Hodge--Tate.  Those claims are not part of the conditional
carrier theorem.

18 Companion records and limits

Read `REPORT.md`, `PROOF_AUDIT.md`, `CLAIM_MAP.md`, `CLAIM_STATUS.json`, and `REPRODUCE.md` under `formal_preservation/readable/checked_conditional/`. The later residual attempt remains separately under `formal_preservation/readable/later_residual_attempt/` and `status_records/`. The inherited Block 27 and residue-counting materials remain in `inherited_baseline/`.

The principal reader scripts are `publication/build_publication.py` and `verification/run_checks.py`. Package integrity is checked by `verify_release.py`. The dated final review records failed attempts as well as completed checks. A successful package verification does not replace a mathematical proof review or a new pinned Lean build.

The current monograph includes the recovered 23-entry bibliography with separately recorded identity checks. This guide adds exact internal source routes. Bibliography identity checks do not certify every external theorem. Universal companion existence, unknown carrier existence, unrestricted local attachment, and universal automorphic occupancy are outside the delivered conditional theorem. No new result about those existence problems is claimed.

Tame and Wild Packet Geometry

The formal companion to Chapter XI explains the declared hypotheses, theorem correspondences and evidence boundaries.

IN THIS COMPANION

Formal companion 2385

Return to Chapter XI

Reading scope

This companion explains the formal mechanisms and their arithmetic interfaces. The general realization endpoint is Conjecture 66. Detailed proofs, construction notes and evidence records accompany the sources.

CHAPTER 1

Reading the formal companion

Chapter XI develops packet decomposition, finite representation comparisons, actual arithmetic/type adapters, and a conditional comparison interface. This guide makes the logical boundaries visible in the source language. The mathematical text gives the exposition. The visual guide illustrates the constructions. The retained Lean sources provide the formal statements and proofs at their printed hypotheses.

The general arithmetic realization endpoint is presented as **Conjecture 66**. Conjecture 66 isolates the missing realization claim from historical Claim 16.2, indexed as original obligation 66. This separation preserves the proved finite comparison and the proved conditional implication. It records that finite assembly and coherent transport have not yet supplied an actual supercuspidal realization in the original generality.

The source collection includes detailed proofs and construction notes. It distinguishes established results, conditional results and the remaining obligations of Conjecture 66.

1.1 What Lean certifies

Acceptance by Lean checks that the declared conclusion follows from its binders, imported declarations, and foundational axioms. It does not silently instantiate a local field, an arithmetic type, a reference correspondence, or a normalized local-factor convention. Those objects must appear in the source or in a separate mathematical attachment.

A structure may contain an existence field. A theorem that consumes that structure proves an implication using the field. It is still a substantive theorem when the comparison map, descent or uniqueness is constructed. It is not a proof of the structure's arithmetic existence. In particular, `Realization.exists_atom` is an existence input in the formal comparison interface.

1.2 Evidence available for this guide

The catalog identifies the selected modules, source hashes, imports and named declarations. Compiler and axiom records specify the exact formal checks. Producing the PDF is a separate operation and does not itself execute Lean.

> The compiler record covers all 423 selected modules with unchanged source hashes. All 4,342 catalogued names resolved to their recorded owners, including four private or local source names matched through Lean's private-name map. The terminal and the single-candidate comparison supplement are separate checked targets.

Population	Modules	Cataloged names	Logical declarations
Selected sources	423	4,342	7,672
Recovered terminal	1	0	51
One-candidate supplement	1	1	1

The last column is the complete population of logical declarations owned by the named modules in the imported private kernel environment. It includes generated and private logical declarations. It is distinct from the retained lexical catalog, and is not a count of independent mathematical discoveries. The audit separately lists 1,636 compiler-only auxiliary names for the selected sources. These are absent from the kernel constant map.

Every audited declaration's transitive axiom dependencies belong to `Classical.choice`, `Quot.sound`, and `propext`. No forbidden dependency was found. All three aggregate imports passed. Two isolated negative controls were rejected as intended: uncataloged public and private custom axioms in a module with a safely cataloged theorem, and a deliberately unresolved catalog name. These fixtures are not Paper XI modules. The supplement's observed axioms were `Quot.sound` and `propext`.

1.3 How the catalog is selected

The selected formal source contains 423 distinct module paths and 4,342 named lexical declaration commands. Identical repeated files are collapsed. The catalog records the origin and exact bytes of each module.

This is a source census, not a count of independent mathematical discoveries or kernel-generated declarations. Constructors, recursors and unnamed instances are outside this lexical count. The historical “65/66” number concerns original paper obligations, whereas the appendix includes many supporting definitions and lemmas. The conjecture is not counted as a Lean theorem.

1.4 Supplement: the comparison of one supplied candidate

The publication comparison fixes one admissible candidate and one admissible reference. A separating factor system identifies their isomorphism classes if their declared factor profiles agree. The additional module `PaperXI.SingleCandidateComparison` applies `LocalFactorIdentification.class_eq_iff` to exactly these supplied objects.

The expected factor profile is a parameter. H5 is assumed only for this candidate. The proof does not consume `Realization.exists_atom`, does not quantify H5 over every realizer, and does not instantiate an arithmetic correspondence. The separating factor system and admissibility conditions remain explicit inputs. This is a formal presentation of the chapter's conditional implication, not an additional arithmetic existence result.

The complete supplementary module follows. It is counted separately from the 423-module catalog and forty teaching excerpts. Its compiler and axiom record accompanies the sources.

end PaperXI.SingleCandidateComparison
```

1.5 The corrected moving-space phase domain

In odd residue characteristic, the monograph's breakwise formula now applies to $M = \mathrm{im}(g - I)$ and its break summands, with g explicitly symplectic and fixed-point-free on M. The selected theorem `PaperXI.BreakOddPhase.source` already proves this product of moving phases. `BreakMoving` supplies the complement and nondegeneracy facts. A zero moving space contributes one. This source alignment does not add an order-prime-to-p hypothesis and does not modify the retained Lean module.

1.6 Reading literal excerpts

A displayed declaration excerpt retains the exact source text through a top-level `:=`, omitting its subsequent proof or value. Named-argument assignments inside binders do not terminate the excerpt. Structures retain all their fields. The complete declaration is available in the source file. A proof excerpt is a contiguous source slice. Ambient assumptions are explained beside it and retained as raw setup lines in `EXCERPTS.json`. Imported definitions remain necessary.

The display is not a separately compiled replacement module. Unicode supported by the monospace font appears directly. Unsupported glyphs use reversible `[U+XXXX]` tokens. The raw excerpt, display file, conversion map and SHA-256 hashes are included.

Navigation through the five readers

The formal core, the written arithmetic constructions and the research arguments have different evidence. The companion links them while keeping the selected source, terminal replay and single-candidate lemma distinct. None supplies an axiom of arithmetic existence or a count of new discoveries.

Question	Reading route and formal boundary
The finite comparison	Monograph finite tame package. Its finite statement and its arithmetic interpretation retain distinct hypotheses.
The existence field	Monograph Conjecture 66, progress Section 1 and Plate XI.1. The source field `Realization.exists_atom` remains an input.
The pointwise comparison	Comparison of one realized candidate. H5 is about that candidate. The more general formal interface's all-realizers binder is not a stronger publication conjecture.
Ordinary arithmetic progress	Monograph Section 19 and the separate progress paper. The explicit parameter, character, conductor and marking arguments are not newly Lean-certified here.
Worked interpretation	Core visual guide and research atlas. Abstract finite examples are not certificates for an unspecified arithmetic type.

The source catalog identifies all 423 module paths, 4,342 named lexical declarations and forty teaching excerpts. Compiler and axiom records state their own checked targets. A source census and a kernel check have different scopes.

Evidence boundaries

Compiler and same-kernel records certify specified source inputs and dependencies. Producing and reviewing the readers is a separate operation. No independently implemented proof checker is claimed.

The terminal's checked source makes its imports, implicit arguments and standing hypotheses explicit. Its status is separate from the 423-module selection. The target is restricted tame Weil-side attachment. It does not construct a general wild automorphic realizer.

The selected classical-source gap has been closed. The Henniart–Lemaire induction interface has now been checked against the full official text, including direct visual inspection of the relevant normalization formulas. The bounded review preserves its characteristic, rank, genericity and orbit hypotheses. Other Bushnell–Kutzko, conductor, tower and descent inputs retain their own evidence. This source check is not H5 or corrected-character occurrence.

Four open obligations, not four missing formal lemmas

General arithmetic realization requires an actual common host with the declared actions and transports. H5 requires the characterizing factors for that same realizer. The corrected-character branch still needs occurrence in its fixed candidate. Where the stronger native contract is prescribed, the actual square, section and honest-phase certificate must be computed on the chosen type. The research certificate plate deliberately leaves those arithmetic fields uncomputed.

The positive transported-marking contract remains separate. Its hypotheses are not silently strengthened by the native-marking task. Likewise, a failed original carrier does not exclude every permitted enlarged inducing carrier.

Reproducible reading routes

CHAPTER 2

Fourier projectors and Frobenius transport

The cyclic packet is constructed by averaging against an additive character. Idempotence, orthogonality and completeness are consequences of the representation law and character orthogonality. The packet space is the actual range of the computed projector, and Frobenius transports that range by its conjugation law.

2.0.1 The averaging operator

The ambient cyclic representation and hypotheses on the additive character are declared in the source module. The index is a residue label in $\mathbb{Z}/M\mathbb{Z}$. The scalar field is C, so the finite order is invertible. The definition sums actual operators. Later results compute their products rather than postulating a family of orthogonal idempotents.

E01: `PaperXI.FourierProjectors`, source lines 13–15.

Contiguous source proof excerpt.

Source SHA-256: `02af62a8c8e5753ef7a695629d44c71db407211d18a6bd6b6a48865ba731de52`.

```

    (ψ : AddChar (ZMod M) K) (j : ZMod M) : Module.End K V :=
  PaperXI.FourierCovariance.fourierOperator (operator ρ) ψ j

```

2.0.2 Completeness of the packet resolution

The finite cyclic group and primitive character remain fixed. The sum ranges over all residue labels. Completeness says that every vector is the sum of its packet components. A vanishing packet is permitted, and the theorem does not assert that every residue label occurs.

E02: `PaperXI.FourierProjectors`, source lines 68–77.

Contiguous source proof excerpt.

2.0.3 An actual packet equivalence

The supplied invertible Frobenius operator satisfies the declared conjugation relation with the cyclic inertia action. The multiplication direction in the residue label is fixed by that relation. The operator and its inverse restrict to the two computed packet ranges. Their inverse identities give a linear equivalence, so equal packet dimensions follow from a constructed transport.

E03: `PaperXI.PacketTransport`, source lines 62–66.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `dc7282e77c935ca61b8807fe87f4fe2fa372d720a28d0a1c8982c6c749e1a910`.

    packet ρ j ≃ₗ[ℂ] packet ρ ((q : ZMod M) * j) where
  toFun v :=
```

2.1 Geometric Frobenius convention and the publication repair

The geometric convention is

$$\Phi^{-1} t \Phi = t^q, \qquad \Phi P_j \Phi^{-1} = P_{qj}.$$

Under the other relation $\Phi t \Phi^{-1} = t^q$, the correct label is $q^{-1}j$. The original Proposition 3.1 proof paired that other relation with the geometric label qj. The mathematical text repairs the displayed relation to the geometric convention, preserving its intended packet transport. The checked Lean module already states both conventions separately. No new Lean proof is claimed for this prose convention repair.

2.1.1 The existing geometric covariance theorem

The cyclic order is nonzero. The element q is a unit modulo that order, and the source hypothesis uses the conjugation by F^{-1}. This exact signature and proof support the publication correction. They distinguish the Frobenius direction from its action on projector labels, rather than changing both directions simultaneously.

E04: `PaperXI.TameProjectors`, source lines 45–52.

Contiguous source proof excerpt.

CHAPTER 3

Induction, return scalars and tensor interactions

The induced representation branch uses a degree homomorphism and its degree subgroups. A normalized degree-one element gives coset representatives. Its cyclic action has a closing scalar determined by the inducing character. Tensor interactions are constructed as actual representation equivalences indexed by greatest-common-divisor classes.

3.0.1 The closing scalar is derived

An actual character of the degree subgroup and a degree-one Frobenius element are supplied. The degree n is positive. The scalar evaluates the character at the full return element. It is not an independent certificate whose agreement with the action is assumed.

E05: `PaperXI.InducedCycleInvariants`, source lines 33–33.

Contiguous source proof excerpt.

Source SHA-256: `2faaeb89211dca9d88df443a27ad69ab7e310783d4e07a3ad54d85c3c5bcae1a`.

```
33 def returnScalar : ℂˣ := ξ (degreePeriod φ δ hφ)
34
```

3.0.2 Dimension and characteristic polynomial

The basis of the genuine degree-induced space has already been constructed. Finite dimensionality and the nonzero degree hypotheses occur in the module's setup. The resulting dimension and polynomial record the entire cyclic block, including its closing scalar. Their interpretation as arithmetic local data needs the corresponding group and normalization attachments.

E06: `PaperXI.InducedCycleInvariants`, source lines 75–77.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

```

3.0.3 The tensor decomposition is an equivalence

Two positive degrees and two characters of their degree subgroups are supplied. Representatives use φ^{-i}, fixing the direction of the shifted interaction character. There are $\gcd(n,m)$ interaction blocks of degree $\operatorname{lcm}(n,m)$. The source builds an intertwining equivalence of representations, not merely the dimension identity $\gcd(n,m)\operatorname{lcm}(n,m) = nm$.

E07: `PaperXI.TameTensorSource`, source lines 66–69.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

```

CHAPTER 4

Finite conductors and the tame comparison package

The finite conductors are sums of codimensions of fixed spaces for a declared subgroup family. Arithmetic Swan and Artin conductors require that this family and its weights match the arithmetic ramification conventions. The finite residue Gauss phase is also a declared character sum before its arithmetic interpretation.

4.0.1 A declared finite ramification sum

The representation, a finite set of depths, a subgroup at each depth and rational weights are supplied. The source does not construct an absolute Weil ramification filtration here. These inputs determine the exact finite sum. The tame vanishing theorem applies when the selected positive-depth groups act trivially.

E08: `PaperXI.TameConductor`, source lines 56–58.

Contiguous source proof excerpt.

Source SHA-256: `808eb443d2a292fc79cd70ce323c369acd62c38e9393ec4c19269dc06d575dcf`.

```

4.0.2 Proposition 16.1 at finite scope

The exact induced spaces, degree character, cyclic relation, inertia label, finite-depth subgroup data and residue characters are supplied. The additive character is nontrivial. The package derives observations, a tensor equivalence, the total tensor dimension and the magnitude of the Gauss phase. Its magnitude formula retains the exception for the trivial multiplicative character. This finite statement does not certify standard local-Weil factors or an arithmetic epsilon-factor normalization.

```

CHAPTER 5

Heisenberg actions, central products and phase comparison

A finite Heisenberg action combines translations and modulation operators. Irreducibility is proved from those actual operators. Break assembly uses a genuine quotient central product and a tensor carrier. To extend the bridge through a stabilizer, the retained action on the whole central extension and the scalar discrepancy must both be controlled.

5.0.1 The finite Schrodinger action

The finite Heisenberg group and its central character are fixed by the source's preceding constructions. The carrier is literally a function space. The multiplication law is checked for the displayed operators. Invertibility, central action and irreducibility are subsequent consequences.

E10: `PaperXI.HeisenbergRepresentation`, source lines 14–16.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `386317cf254a374627df755dc02465986fc602151303b4e2b3413f2b82b46492`.

16   toFun a :=
```

5.0.2 Irreducibility from actual translations and modulations

The source supplies the required nondegenerate character pairing. Its invariant-subspace proof uses coordinate projections and spans the full function space. This finite representation theorem supplies a building block. It does not by itself embed the block in a canonical arithmetic simple type.

E11: `PaperXI.HeisenbergRepresentation`, source lines 58–59.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `386317cf254a374627df755dc02465986fc602151303b4e2b3413f2b82b46492`.

59     (h2 : (2 : K) ≠ 0) : Representation.IsIrreducible (representation (X := X) ψ h2) :=
```

5.0.3 The assembled group is a quotient

A finite indexed family of central-extension data shares a declared center. The balanced central subgroup is defined earlier in the module. The quotient construction retains an explicit center even for an empty family. The quotient's representation must descend through the balancing relation, and that descent is proved in the supporting modules.

E12: `PaperXI.CentralProduct`, source lines 39–41.

Contiguous source proof excerpt.

Source SHA-256: `9d1e6a4ece84a862ef75383b66b97af694c9ac2298fc2047a6c4844bc6aa34af`.

42
```

5.0.4 Precisely what break assembly consumes

The finite family includes the actual groups, quotient groups and complex carriers. Its record keeps central extensions, retained lifts, central characters and relevant pairings. An initial tensor intertwiner and a final representation equivalence are not input fields. They are constructed. Dyadic square and retained-group data remain part of the input and cannot be recovered from an alternating commutator form alone.

E13: `PaperXI.FiniteBreakAssembly`, source lines 22–37.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `ecca3693f7733c7ceef597b6e821b111610c82d612fd66abfe754af0e5be434c`.

```

CHAPTER 6

Odd phases and dyadic quadratic refinements

The chapter separates odd phases defined by a determinant from dyadic phases defined by a quadratic refinement. The formal certificate computes the declared determinant phase through its characteristic polynomial. Identifying that value with an arithmetic Weil trace or a canonical beta extension requires an additional argument. In residue characteristic two, an alternating form alone does not retain the quadratic data needed for the phase.

6.0.1 The actual polynomial phase certificate

The residue characteristic is an odd prime. A finite-dimensional vector space carries an actual nondegenerate alternating form. The supplied invertible linear operator need not be fixed-point-free for this algebraic identity. The form derives even dimension. Evaluation of the actual characteristic polynomial at one gives the determinant of the difference operator with the declared sign convention. This certifies the defined phase, without assuming that it equals a separately normalized arithmetic phase.

E15: `PaperXI.OddPhaseCertificate`, source lines 46–50.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `783d84147c4f09cbca432ad799b1e57d9bd47da13f3841e92d4f071d49709f2e`.

```

      quadraticChar (ZMod p) (g.toLinearMap.charpoly.eval 1) :=
```

6.0.2 Refinements form an affine space

Two quadratic refinements have the same bilinear form over the field with two elements. Nondegeneracy is not required for the affine-difference statement. Their difference is uniquely linear. Hence the bilinear form does not choose one refinement. When the arithmetic contract prescribes square data or a whole marked finite extension, that datum must be retained.

E16: `PaperXI.DyadicAffine`, source lines 74–75.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `06fd5b5a57b17060abd22a11fb29592fcd53b06aa09388b92314fe2fd23692e3`.

```
theorem exists_unique_linear_difference (q q₀ : Refinement b) :
    ∃! l : V →ₗ[ZMod 2] ZMod 2, addLinear q₀ l = q :=
```

6.0.3 The exact Arf Gauss sign

The finite index set parametrizes symplectic planes. Each plane has the explicit coefficients of its quadratic refinement in the field with two elements. The integer character sum is $(-1)^{\mathrm{Arf}(q)}2^d$. The proof factors the complete finite sum into plane sums. It is an exact theorem, not an asymptotic or fitted numerical rule.

E17: `PaperXI.DyadicGauss`, source lines 51–58.

Contiguous source proof excerpt.

Source SHA-256: `634fe67a476f515f627455fa43a1ec870a4ccc66b87867cc5d40ee1227c91dea`.

```

CHAPTER 7

Matrix holonomy and global section equivalence

Local packet comparisons can be transported around a graph. A rooted spanning tree determines root paths. The remaining original edges become chords. Full matrix compatibility on the resulting fundamental cycles is the necessary and sufficient obstruction to a based global gauge.

7.0.1 The rooted chord criterion

The graph is a connected quiver with invertible edge transports. A root comparison is fixed. The cycle condition is an equality of the full transported linear maps. Trace, determinant and projective cycle tests are weaker than this matrix identity. The source constructs a gauge precisely when the chord tests hold and derives compatibility on every edge.

E19: `PaperXI.GraphGauge`, source lines 155–159.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `1750d323d264d4760717c62ab3aa154cbebefcdd24e80cc76ef22d7d8f5a572b`.

      ∀ e : GraphTree.Chord (GraphTree.ofConnected r hc),
        CycleCompatible A B U (GraphTree.rootPath (GraphTree.ofConnected r hc)) e.val :=
```

7.0.2 The space of compatible sections

Each vertex has a vector space fiber and each directed edge carries a linear equivalence. A section satisfies every edge equation. The space is an actual linear subspace of the product of fibers. It can be zero. A nonzero section space, an irreducible section representation, and an arithmetic supercuspidal atom are separate assertions.

E20: `PaperXI.GluedPacketSections`, source lines 22–26.

Contiguous source proof excerpt.

Source SHA-256: `5bf8047d59226ed80f93c4668b031aedab1df38bd5ee39456a9335f2685372bf`.

CHAPTER 8

Monodromy and conditional atomic reconstruction

Finite atomic results can propagate through a supplied decomposition and a supplied ordered-quotient interface. The reconstruction theorem constructs sorting, atomic replacement and descent. The external decomposition and ordered Langlands-quotient existence statements remain printed hypotheses.

8.0.1 The monodromy normalization

A twisting character ν and a representation are fixed. Copy i has the twisted action $\nu(g)^i\rho(g)$, and the nilpotent operator shifts copy index. The declared relation is $R(g)NR(g)^{-1} = \nu(g)^{-1}N$. The inverse on the twisting character fixes the convention. Changing it would change the normalization.

E22: `PaperXI.MonodromyAtom`, source lines 64–66.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `f53d79ddc74c43995955bc45c8bce600d821bb6d118e9426d85e8478c0829bf2`.

CHAPTER 9

Local rings, ramification projectors and normalized Frobenius

The later local-field branch attaches finite residue extensions and normalized geometric Frobenius to actual algebraic objects. Lower ramification projectors average genuine finite groups. Their successive differences form depth-detail channels. A degree-only quotient forgets inertia, and the source proves exactly which detail information then vanishes.

9.0.1 Lower congruence groups

The action is on a supplied local ring, with the powers of its maximal ideal. In a finite Galois DVR application these agree with the usual nonnegative lower groups under the stated dictionary. The generic definition is based on congruences of the actual action. It is not asserted to be an absolute Weil ramification filtration without the arithmetic attachment.

E25: `PaperXI.ValuationRamification`, source lines 15–28.

Contiguous source proof excerpt.

Source SHA-256: `92ddb509dc327389c2168f44ddfd5f7e16f4315af16835a54398077fe81146ca`.

```

```

9.0.2 An exact depth-detail resolution

The finite-group ramification filtration, representation and stabilization hypothesis are supplied. Averaging is over actual finite subgroups. Nested fixed spaces give nested projectors. Their successive differences are orthogonal detail projectors, and the telescope reconstructs the identity at the stated stabilized depth.

E26: `PaperXI.RamificationPolyphase`, source lines 311–313.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

9.0.3 The unconditional quotient target is the degree range

The residue–Frobenius pullback has a degree homomorphism whose kernel is inertia. No degree-one lift is needed for this first-isomorphism statement. The quotient is equivalent to the image of degree. To replace that image by all integer degrees, the source adds a hypothesis of a degree-one Frobenius lift or a subsequent construction that supplies it.

E27: `PaperXI.RamifiedUnramifiedQuotient`, source lines 42–43.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

CHAPTER 10

Arithmetic type and induction adapters

The arithmetic branch uses actual local fields, continuous coordinate equivalences, literal subgroups, original characters, and induction carriers. Generic support and intertwining arguments derive irreducibility once the type dictionary is supplied. Later continuations reduce some dictionary leaves to quotient forms and actual lattice algebra.

10.0.1 A candidate from three arithmetic profile leaves

The ambient setup fixes local fields F, E, coordinates, the literal subgroup D, its character θ, the prescribed κ, residue representation σ, and the original tensor carrier. The displayed hypotheses keep trace support, character covariance and the oriented ambient index identity explicit. The proof derives the required Heisenberg intersection dimension and feeds it into the inherited candidate constructor. It preserves the original carrier and representations. The existence of canonical type data and the actual truth of its retained source hypotheses are separate mathematical attachments.

E29: `PaperXI.ActualProfileCandidate110`, source lines 34–88.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `dd434e182eec32397e64a3e6a43193cc56a3c965eff65c4e36e14f4bd0b2c27b`.

10.0.2 The residue-rank-one specialization

The residue rank is Fin 1. The original character, carrier, support dictionary, beta-extension intertwining and occurrence input remain fixed. The finite cuspidal residue factor and several normalization/support leaves are derived in this branch. It still does not manufacture every canonical simple character or establish the entire original claim.

```

10.1 Why orientation matters

For the literal pair group, $\iota(b) = g\iota(a)g^{-1}$. The first coordinate therefore belongs to

$$I_g = \{a : g\iota(a)g^{-1} \in \iota(K)\}, \qquad \iota(I_g) = \iota(K) \cap g^{-1}\iota(K)g.$$

The scalar intersection uses the same orientation. Under whole-action irreducibility and the original scalar/trace profile,

$$d^2 = [K : H].$$

The positive oriented index identity $[K : I_g] = [H : C_g]$ then yields $[I_g : C_g] = d^2$, giving the one-dimensional intertwining space. Schur is applied to the whole irreducible action, not to arbitrary intersection restrictions. Infinite subgroup index is encoded by zero in the relevant natural-valued index API, so positivity is essential to cancellation.

CHAPTER 11

Morita lattices and exact one-plus comparisons

The centralizer coefficient ring acts inside a potentially noncommutative endomorphism ring. It must not be treated as central in the full ambient algebra. Morita corner arguments produce bases, coordinate quotient equivalences and actual additive indices. Multiplicative one-plus indices require genuine group closure and a common deep ideal.

11.0.1 The actual Cartan index

Actual ring homomorphisms embed centralizer matrices in the endomorphism ring. The finite/full lattice and radical-commutation conditions are explicit. The index follows from actual coordinate conjugation and the preceding quotient computation. A numerical index formula is not inserted as a premise, but the arithmetic lattice instance must satisfy the printed hypotheses.

```

11.0.2 From additive lattices to unit groups

The source keeps the original integral-order ring and its actual one-plus subgroups. A common ideal and a finite quotient allow the exact coset comparison. An arbitrary additive lattice is not automatically a subgroup under $1 + x$, and a conjugate lattice need not be an ideal of the full field algebra. The theorem's carrier and group hypotheses prevent either substitution.

E32: `PaperXI.OnePlusIntersection110`, source lines 179–189.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `512e3b7a894d7db7474f8586c4c652dddd45bfd98197f637f7be8e5a8fec3e7e`.

CHAPTER 12

Complex scalar cochains and honest cyclic actions

Equal scalar commutators determine a complex scalar cocycle class under the stated divisible-coefficient hypotheses. This can construct an actual representation of a supplied group. The original retained finite-group lift and the arithmetic source attachment remain separate when more structure is prescribed.

12.0.1 What equal commutators supply over complex units

The two normalized cocycles have coefficients in $\mathbb{C}^\times$. Their commutators agree. A cochain is constructed whose coboundary gives the cocycle ratio. This scalar-pushout result does not identify distinct marked finite central extensions such as the dyadic retained-group examples.

E34: `PaperXI.ScalarCocycle112`, source lines 171–174.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

      ∀ a b, c.coeff a b = (s a * s b / s (a * b)) * d.coeff a b :=
```

12.0.2 The equivariant actual-group action

The actual groups and their full automorphisms are supplied. The scalar bridge has been corrected using the explicit cyclic coprimality conditions. The result retains the original theta restriction and intertwines the prescribed packet generator. It requires full actions, not only an action on the symplectic quotient.

E35: `PaperXI.EquivariantRepresentation113`, source lines 67–91.

12.0.3 Determinant-one normalization

The generator implements the supplied full automorphism on the same irreducible carrier. Its cyclic order and carrier dimension satisfy the required coprimality. Scalar rescaling can impose order and determinant normalization with uniqueness at the stated scope. The theorem does not identify the implementer with the independently prescribed arithmetic beta extension.

E36: `PaperXI.CyclicNormalization113`, source lines 167–173.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

CHAPTER 13

Conjecture 66 and the surviving conditional comparison

The finite bridge, coherent graph equivalence, arithmetic realization and local-factor characterization are distinct assertions. Conjecture 66 concerns general arithmetic realization. Conditional comparison is a theorem once actual realization and the stated factor characterization are supplied.

13.0.1 The factor profile must characterize the declared range

An atom type, its isomorphism setoid, a test type and value type are fixed. The record contains admissibility, invariant profiles and separation on that admissible range. The separation field is the external characterization input. In an arithmetic application, all normalizations and the original characterizing family must be instantiated. A finite-group character instance is an example of the abstract interface, not a local-Weil converse theorem.

E37: `PaperXI.LocalFactorIdentification`, source lines 14–18.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `3e81e1ce1c7b50d2771432e73d46f02de2a2ce4910e0a3420aa67e6b02a514f3`.

```
structure FactorSystem {Atom : Type*} (s : Setoid Atom) (Test Value : Type*) where
  admissible : Atom → Prop
  profile : Atom → Test → Value
  invariant : ∀ a b, s.r a b → profile a = profile b
  separates : ∀ a b, admissible a → admissible b → profile a = profile b → s.r a b

```

13.0.2 Existence is an explicit arithmetic field

The factor system and allowed datum type are fixed. A realizes relation connects each datum to possible actual atoms. The record's `exists_atom` supplies existence. Neither atom uniqueness nor reference agreement is stored here. General arithmetic existence of this record is the unresolved endpoint.

E38: `PaperXI.LocalFactorIdentification`, source lines 25–28.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

Source SHA-256: `3e81e1ce1c7b50d2771432e73d46f02de2a2ce4910e0a3420aa67e6b02a514f3`.

```
structure Realization (D : Type*) where
  realizes : D → Atom → Prop
  exists_atom : ∀ d, ∃ a, realizes d a
  admissible : ∀ d a, realizes d a → S.admissible a

```

13.0.3 H5 acts on the same realized candidate

An actual realization is supplied. The realized atom's profile and the reference atom's profile agree with the same expected profile on the original test family. Separation then proves equality of atom classes. H5 must refer to this same chosen completion. Replacing it with a factor identity for another candidate would not discharge the displayed hypothesis.

E39: `PaperXI.LocalFactorIdentification`, source lines 49–55.

Contiguous source proof excerpt.

  exact (hreal _ (chosenAtom_realizes S R d)).trans href.symm
```

13.0.4 The full formal conditional signature

The finite source data construct a tensor bridge. Honest actions, phase compatibility and matrix holonomy supply the coherent finite comparison. The allowed target diagram, an arithmetic realization, admissibility and factor profiles are then supplied explicitly. The conclusion contains a concrete compatible gauge, an equivalence of global section representations, and equality of the realized atom class with the reference. The source does not assert realization of every arbitrary finite datum. Its theorem name and successful Lean status must be read together with these hypotheses.

E40: `PaperXI.ConditionalAtomicComparison`, source lines 127–143.

Literal declaration excerpt. A proof/value after a top-level assignment is omitted; structure fields are retained.

```

13.1 The publication statement

Fix the declared class $\mathcal{A}$ of wild atoms and the paper's normalizations. For every $\rho \in \mathcal{A}$ with supplied H1–H4 assembled finite packet datum d_ρ, Conjecture 66 asserts that there exists one actual admissible supercuspidal representation π of $\mathrm{GL}_{\dim \rho}(F)$ together with an arithmetic realization witness $R(d_\rho, \pi)$, recovering the prescribed packet and preserving the declared stabilizer action, central-extension/phase data, and compatible transports. This witness uses actual arithmetic inducing data and explicit comparison/recovery. It does not require the whole assembled packet to be the original maximal-simple-type quotient.

Given that same π and realization witness, the conditional comparison proposition assumes original H5 for π on the stipulated characterizing family with the fixed normalization. The supplied characterization then gives $\pi \simeq \mathrm{LLC}(\rho)$. This proposition has no claim that H5 produces a candidate, and no requirement that H5 hold for all possible realizers.

The retained general Lean interface has an *all-realizers* profile binder because its `Realization` relation may have several realizers. The publication proposition needs the factor equality only for its one supplied candidate. The pointwise separation lemma `class_eq_iff` gives that implication directly. The broader interface should not be misread as strengthening the publication conjecture.

The mathematical text fixes the realization definition, admitted source class and finite hypothesis data. General arithmetic realization is a conjecture. Factor comparison is conditional. The restricted odd-prime and dyadic constructions are ordinary mathematical results under their stated hypotheses. The formal companion adds neither an axiom for the conjecture nor a placeholder proof.

The restricted constructions are not Lean-certified local-field and simple-character developments. They retain the same-candidate H5 boundary. The dyadic low-rank enlargement changes the arithmetic assembly carrier while preserving the candidate through induction in stages. It does not enlarge the fixed maximal-type quotient obstructed by the dimension calculation.

APPENDIX A

Complete selected named-source catalog

Every selected module below is copied unchanged into the editable guide's `sources/PaperXI` folder. The catalog gives module identity, selected layer, SHA-256, direct project imports, module documentation and every named lexical declaration with its raw source line. These line pins locate declarations in the complete source, not independently compiled snippets. Earlier repeated source-layer identities remain in `SOURCE_VERSIONS.json`.

# Periodic lattices and their literal first congruence group

The chain used below is the actual sequence of scalar-uniformizer translates
of the integral lattice in `E^m`, viewed as a vector space over `K`. Its first
congruence group consists of automorphisms preserving every lattice and acting
as the identity modulo the next lattice. Uniformizer normalization is proved
from the coordinate definitions. This is not an identification with the
simple-character group of an arbitrary stratum.

```
# Actual unramified base change through the recursive local-field tower

Block 40 proved Frobenius-power and Euler-factor formulas for an internal degree
dilation of the integer-degree unramified Weil model. Block 41 constructs an
actual recursive local-field tower and its restriction map. This module proves
that the two constructions give the same Frobenius polynomials and local
factors, and records conductor zero on both sides of the actual tower.

This remains scoped to the bounded unramified Weil models, not absolute Weil
groups or automorphic base change.

```
Paper XI, Theorem 2.5: choice-independent conditional reconstruction.
External interfaces here are exactly (1) existence and intrinsic uniqueness of
indecomposable source displays and (2) existence and uniqueness of irreducible
Langlands quotients of ordered target factors. They do not contain the final
candidate map. Sorting, atomic replacement, descent, and that map are constructed.
The theorem is conditional on these classical interfaces; it does not formalize
the construction/classification of local Weil groups or p-adic representations.

# Independent scalar tests on fundamental graph cycles

Every assignment of unit scalars to the chords of the constructed rooted tree
is realized by actual one-dimensional edge transport: tree edges carry one and
each chord carries its prescribed scalar. Thus the scalar cycle tests can vary
independently. The same realization gives characters on the actual reduced loop
group and its abelianization.

# Irreducibility of actual subgroup induction from a local coefficient projector

All spaces and actions below are Mathlib's actual `IndV` and `ind`, at arbitrary
subgroup index.  The projection hypothesis is a local group-algebra condition:
each vector's identity-coset coefficient can be isolated by a finite linear
combination of subgroup operators.  The conclusion is actual irreducibility,
not scalar endomorphisms or an assumed simple subrepresentation lattice.

# Comparison of the algebraic and spectral integer rings

For the unramified residue extension constructed in `LocalFieldResidueExtension`,
the finite-extension spectral norm has unit ball equal to the image of the
algebraically constructed complete DVR.  The proof proceeds through the exact
integrality criterion over the base local-field integers.

# Actual intersection intertwining at a normalizer

The intertwining locus is defined by nonzero maps on the literal intersection
subgroup. At a normalizing element such a map is a whole-subgroup intertwiner.
An inclusion of the actual character intertwining locus in that of a prescribed
representation supplies the required map, without a determinant or residue-size
condition. The inclusion is an input; no simple-character theorem is asserted.

# Ramified pullbacks and their inertia-free degree quotient

The residue--Frobenius pullback retains a decomposition-group coordinate and an
integer degree.  Its degree kernel is inertia.  This file proves the precise
first-isomorphism statement and compares the quotient with the integer-degree
unramified model only under an explicit degree-one Frobenius-lift hypothesis.

It also proves the exact representation-theoretic information loss: a
representation pulled back only through integer degree kills every lower
ramification subgroup, so every ramification depth projector is the identity
and every positive detail projector is zero.
```

# Integer-degree base change for the finite unramified Weil model

The finite unramified model is canonically equivalent to `Multiplicative ℤ`.
Multiplication of the degree by `n` therefore gives the restriction map that
models unramified base change of residue degree `n`. This module proves the
resulting Frobenius-power and Euler-factor formulas.

No actual tower of local fields is constructed here; the theorem is scoped to
this integer-degree Weil model.

# Conductor zero for the finite unramified Weil model

This module does two separate things.

* It proves a generic theorem in the existing `ValuationConductor` interface:
  a representation has Artin conductor zero when the actual degree-kernel inertia
  subgroup is trivial.
* It packages the corresponding codimension/Swan/Artin exponents for the finite
  unramified Weil model constructed in Block 39.

The model-specific exponents are not asserted to be the conductor of an absolute
Weil representation. They record the exact unramified specialization of the
existing fixed-space formula.

# Recursive unramified local-field towers

This module constructs the upper field over the already constructed lower field,
using the checked residue-field equivalence to transport a finite residue tower.
The resulting map on the integer-degree unramified Weil models is defined by the
actual relative residue degree.  No absolute Weil group is asserted.
```

FORMAL COMPANION XII

Patching Support and Hecke Packets

The formal companion to Chapter XII explains the declared hypotheses, theorem correspondences and evidence boundaries.

IN THIS COMPANION

Formal companion 2618

Return to Chapter XII

The formal record and the reader

This formal companion follows the mathematical text and visual studies. Its source census contains 96 modules and 1,229 public named declarations. Those are source counts, not a count of new mathematical discoveries.

Three contracts remain distinct

Record	What it establishes
Revised internal claims	The formal sources map all 49 amended claims to checked production targets.
Original wording	The historical census remains 41 complete, seven partial, and one unchecked.
Reader preparation	Checks of source, evidence, finite examples, references, layout, and packaging. No fresh Lean/Lake execution.

The full 49-row table in Appendix B now links to the actual main statements. Each mapped target still has its own displayed binders and source location. A link does not establish definitional equivalence between prose and code.

Read the last two constructions carefully

The companion-completion theorem assumes finite occupied classes, complete separated coefficients, continuous representatives, integral polynomial data, and relations valid in every admissible frame. Visual lesson Plate XII.23 makes the frame distinction concrete.

The five-gate theorem requires a compatible Hecke point, actual ordinary or derived carriers, and realization at the selected eigensystem. Visual lesson Plate XII.17 displays the separate premises. Propagation compares two supplied compatible families for the same automorphic object.

Compiler evidence

Compiler records certify the exact sources they checked. Source inventories, figure calculations and reader preparation have separate scopes. None substitutes for executing the kernel on a new formal statement.

Abstract

This guide explains the complete production Lean source accompanying Chapter XII, with a source catalog, declaration census, import audit, exact source excerpts, and a claim crosswalk. It separates constructed algebraic and topological objects from hypotheses supplied by an arithmetic application. The checked revised contract comprises 49 internal claims mapped to 291 distinct production targets. The original wording remains a separate ledger: 41 complete, seven partial, and one unchecked. The guide preserves all 96 production modules and their inherited verification records. Its new checks are source, provenance, and document checks. No fresh Lean compilation was available in the finalization environment.

1 What this guide certifies and how to use it

The complete formal sources accompany this volume. This companion describes their statements and hypotheses alongside the mathematical text's explicit clarifications. The production theorems and their compiler records retain their separate scope.

Read Sections 4–7 for the completed local and global constructions, Sections 8–12 for support, packets, occupancy and conditional realization, and Section 14 for replay. Appendices list every source module and every revised internal claim. The machine-readable catalog gives full SHA-256 hashes, source locations, imports, declaration names and line numbers. The full production source is supplied. Printing every line in this PDF is unnecessary for reproducibility.

Three distinct kinds of evidence must be kept separate. A Lean kernel check verifies the exact formal proposition under its hypotheses and dependencies. An ordinary mathematical proof explains a proposition in mathematical prose, with its own statement and citation obligations. A finite computation verifies the tested cases, numerical identities or model bounds stated by that computation. Neither a finite numerical certificate nor a scan of source tokens is a substitute for kernel elaboration of the production proof.

The compiler evidence is retained with the corresponding source and object identities. Reader preparation does not execute the kernel. The replay procedure is available with the separately supplied runtime.

2 Independently checked counts and their definitions

The registered manifest contains exactly 96 distinct modules, and its source path set equals the set of all production `.lean` files. There are 91 files under `PaperXII/` and five under `PaperX/`. Directory names alone do not identify originality: `PaperXII.ReuseCompactness` and `PaperXII.ReuseFiniteSeparation` retain Paper X namespaces and 18 reused theorem declarations. Together with 63 theorem declarations in the five Paper X files, these account for the 81 reused theorems. Chapter XII's own public theorem count is 748.

The public named lexical census is 1,229: 829 theorems, 319 definitions, 47 abbreviations, 17 structures and 17 named instances. One private theorem helper, `PaperXII.DeterminantalIdeals.option_factor`, is excluded from the public count. The 829 theorem declarations divide into 748 own and 81 reused. They are supporting lemmas and interfaces as well as theorems implementing numbered manuscript claims. This is not a historical novelty count or a twelve-chapter total.

The independent scanner blanks nested block comments, line comments and strings while preserving line numbers. It recognizes anchored named declarations in each module's unique namespace and resolves their qualified names. Its declaration set agrees exactly with the inherited axiom target set. It finds no production `sorry`, `admit`, `axiom`, `unsafe`, or `native_decide` token outside comments/strings. These are lexical findings. Elaboration and transitive axioms remain the role of the compiler records.

The 49 revised claim records comprise 27 theorems, 14 corollaries, seven propositions and one lemma. Three worked examples, definitions, remarks and eight external standard facts are outside that internal census. All 291 distinct mapped targets occur in the 1,229-name inherited audit. A target can support several claims. A claim can require several targets. Target count is therefore neither theorem count nor claim count.

The original wording has 41 complete, seven partial and one unchecked claim. The eight amendments are 6.12, 9.4, 9.5, 9.6, 10.5, 12.2, 12.4 and 12.6. The amended statements have complete mapped coverage for all 49 claims. That does not relabel the original statements as proved.

3 Source organization, dependency order and hypothesis notation

The source audit finds 113 direct internal import edges. Every internal import names a registered module and precedes its consumer in `checks/modules.json`. The external direct imports are Mathlib modules and `Std`. The complete list is in `data/census.json`. This checks dependency order in the sources, not the entire transitive Mathlib import graph. The production tree reuses Chapter X, not Chapter XI.

The 96 modules consist of 71 foundational modules, ten Fitting modules and fifteen completion modules. The completion group has 146 public theorem declarations and 225 public named declarations. These are source counts. Presenting them here supplies no new proof.

In Lean, arguments in square brackets such as `[CommRingR]` and `[CompleteSpaceP]` are typeclass hypotheses. A proposition-valued ordinary argument such as `(hB:IsAdicmB)` is also a hypothesis. A `variable` command may contribute ambient arguments to later declarations. `include` and `omit` control that contribution. Reading only the line beginning `theorem` can therefore hide essential assumptions. The full exact excerpt modules preserve these commands, imports, namespace and section boundaries.

The source excerpts delivered as `excerpts/*.lean` are byte-identical full modules, including their ambient hypotheses. PDF excerpts select line ranges and retain original line numbers. To avoid missing glyphs in portable code typography, the display copies replace eleven symbols by readable forms, for example `iSup` for the indexed supremum and `/` for Lean's ideal-quotient slash. The complete replacement map is in `excerpts/INDEX.json`. This is a documented display convention only. Production source and exact excerpts retain every original Unicode character.

4 Claim 3.1: construct the tensor, then complete it

For a finite index type ι, commutative coefficient ring O, and commutative O-algebras R_i, the raw tensor is Mathlib's actual `PiTensorProduct OR`. It is not a record accepting an already supplied tensor equivalence. The factor inclusion is `PiTensorProduct.singleAlgHom`. The family lift is constructed from a multilinear product and the tensor's universal map.

Given ideals $m_O \subseteq O$, $m_i \subseteq R_i$, and condition ideals I_i, define

$$S = \bigotimes_{i\in\iota,O} R_i, \qquad \mathfrak{a} = m_O S + \sum_i m_i S, \qquad L = \sum_i I_i S.$$

In Lean the finite sums are indexed suprema of mapped ideals. The scalar term is present even if ι is empty. Removing it would change the topology for the empty family to the wrong normalization.

```

The ordinary quotient map is built by applying the ideal quotient in each factor. Its kernel contains L. Quotient lifts construct both directions between S/L and $\bigotimes_i (R_i/I_i)$. Tensor extensionality and quotient extensionality prove the inverse identities. This produces an ordinary algebra equivalence, with

a proved exact image for the defining ideal. Ordinary tensor right exactness alone would not establish the completed theorem.

`AdicModel.CarrierRI` is a type synonym that installs the specified ideal-adic topology on R. Its `Completed` object is the actual Hausdorff uniform completion of that carrier. The forgetful raw ring equivalence does not assert continuity into an arbitrarily chosen topology. This prevents the topology from being replaced silently.

Source: `PaperXII/AdicModel.lean`, lines 12–42.

Thus `CompletedTensorRmOm` is the Hausdorff completion of S in the literal $\mathfrak{a}$-adic additive uniformity. Its O-algebra structure comes from the dense embedding of S, and its completed factor maps compose that embedding with the raw factor inclusions. The condition ideal is the closure of the algebraically extended L.

5 Completion and quotient: actual maps, completeness and inverses

The reusable comparison is

$$\widehat{R}\big/\overline{I\widehat{R}} \;\cong\; \widehat{R/I}.$$

Its ambient assumptions are a commutative ring, a uniform space with uniform additive group, and a topological ring. Countable generation of the additive uniformity is used to prove completeness of the quotient of the completion. There is no assumption supplying completeness of that quotient, an inverse comparison map, or comparison surjectivity. The closure makes the quotient Hausdorff.

The forward map extends the actual quotient map. Its continuity and the target's separation prove that it kills the closed extended ideal. The backward map first descends the dense raw representatives, then extends from R/I to its completion. The source quotient has its actual quotient topology and the associated additive uniformity. `PaperXII.AdicQuotientTopology` separately proves that this quotient topology is the topology of the image defining ideal.

The inverse laws are proved on dense representatives and extended by continuity. The second law uses quotient surjectivity after completion induction. The ring equivalence and its homeomorphism are then constructed from these proved maps.

The source theorem `closedConditions_eq` identifies the ideal with the literal closure of the ideal generated by the completed factor images. The supplementary consumer `exact_completed_kernel` additionally asserts exact equality of the kernel of the canonical completed map and the stated closed ideal. That consumer is separate from the production theorem census.

The general comparison requires neither locality nor Noetherianity of the raw tensor ring. `PaperXII.AdicCompletionComparison` independently identifies the uniform completion with Mathlib's algebraic inverse-limit adic completion. Finite generation controls ideal powers and identifies the completed topology with the topology of its extended defining ideal. These steps support the subsequent specialization to local rings.

6 Locality, universal maps and the edge cases

For the manuscript specialization, supply a field k, an O-algebra structure on k, residue algebra maps $R_i \to k$, and surjectivity of $O \to k$. The defining ideals are their kernels. `PaperXII.FiniteTensorLocality` constructs $S/\mathfrak{a} \cong k$, proves $\mathfrak{a}$ maximal, and derives finite generation from Noetherianity of O and each R_i. It then proves locality and the maximal-ideal-adic topology of the actual completion. These residue maps are explicit mathematical data, not an implicit assertion that all residue fields somehow agree.

The completed universal map also has explicit topological control. Its target P is a complete Hausdorff uniform topological ring with O-algebra structure, m_P-adic topology, and factor maps carrying both the scalar and factor defining ideals into m_P. The raw family map is proved continuous, extended to the actual completion, and shown unique by density and finite tensor extensionality. The final theorem on existence and uniqueness is an output of that construction.

The empty family retains m_O's adic topology. Zero conditions give the identity comparison. A unit condition produces the zero ring and still satisfies the ring comparison. Locality of a quotient is claimed only with an explicit nontriviality premise. The zero ring is not assigned the manuscript's nonzero local ring and residue field. Source boundary checks cover these cases separately.

7 Claim 3.3: completed global base change and its points

Let A be the constructed completed local tensor, let J be its closed condition ideal, and let C be the independently completed tensor of R_i/I_i. The A-algebra structure on C is built from the proved Claim 3.1 equivalence $A/J \cong C$. `quotientIdentification_ideal` proves that the transported defining ideal is the one defining the actual condition tensor topology.

Given the supplied global ring B and its structural A-algebra map, the global condition ring is the actual completion of $B \otimes_A C$. The transport code first constructs the tensor with A/J, then transports along the proved quotient identification. It is not an assumed pushout with a supplied point-factorization field. For complete B, the actual ring is bicontinuously identified with $B/\overline{JB}$, and its canonical global map is surjective.

The reusable ring-point theorem assumes finite generation of the scalar and factor defining ideals, B's declared adic topology, and an ideal bound for the structural map. Its target is a complete Hausdorff uniform topological ring. It proves that a unique continuous point factor exists precisely when each original local restriction kills I_i.

The manuscript capstone uses Noetherianity and common residue maps to supply finite generation. It requires B local and the structural algebra map local. The resulting maximal ideal bound is proved internally. Locality is an essential premise here. A bare continuous ring map is not the full printed capstone's input. The final traditional manuscript exposes these inherited conventions directly in Claim 3.3 and spells out the point category rather than relying on conventions elsewhere.

For continuous local O-algebra points, the production point theorem additionally has B complete, actual O-algebra structures on B and P, and an original point which is an O-algebra map reflecting units. The completed global coefficient action is the actual composite through B. Surjectivity of the global map proves that the unique ring factor reflects units. Equality on coefficients proves it is an O-algebra map. Naturality follows from equality after the surjective global map.

The ring-point result, local algebra-point result and Noetherian/local specialization are distinct declarations and must be read together. A local deformation test point is distinct from a characteristic-zero field specialization, where a coefficient uniformizer can be a unit. Continuity of the specialized representation is separately required by realization. The supplementary `claim33` consumes the local point statements using hypotheses from the manuscript, without an extra finite-generation or ideal-bound hypothesis. It does not prove arithmetic representability of a deformation functor. Representability, universal arithmetic deformation representations, and existence of the local quotient rings remain supplied inputs.

8 Ordinary support, patching and intrinsic Fitting ideals

For a finite module, production support is Mathlib's actual localization support on the prime spectrum. Lean proves

$$\operatorname{Supp}_R M = V(\operatorname{Ann}_R M).$$

Under the Noetherian hypotheses, near faithfulness is equivalent to full support. Quotient support is obtained on corresponding primes using actual quotient modules and localization/Nakayama arguments. Ordinary patching then uses supplied coefficient and module control isomorphisms to descend full support from the patched finite module. Finite generation and finite-level full support are outputs.

An arithmetic patching theorem supplying the patched ring, module, control maps and full patched support remains external. The finite-level R-action on the same carrier must be restriction of its Hecke action through the supplied comparison, as expressed by the ambient scalar-tower hypotheses. Derived carriers require the corresponding transport of the actual complex. Two unrelated actions on a carrier do not supply this compatibility. Freeness over an auxiliary algebra is insufficient for full deformation support. The power-series counterexample demonstrates the missing implication. A ring isomorphism $R \cong \mathbb{T}$ transports existing support. A surjection alone can erase a component, as in the actual node $k[[x,y]]/(xy)$ followed by quotienting by (x).

The Fitting block of ten modules constructs the determinantal ideals of a finite presentation and proves their invariance under changes of presentation, generator and relation counts. Its intrinsic definition chooses a presentation using classical choice and then proves equality with the minors of every actual finite presentation. No theorem on presentation independence is supplied as a hypothesis.

```

The arbitrary base-change theorem transports each minor under the ring map. The support criterion and all higher strata are stated for finitely presented modules. Noetherianity plus finite generation in the manuscript supplies that premise. For a presentation with n generators,

$$\dim_{\kappa(\mathfrak{p})}(M \otimes \kappa(\mathfrak{p})) = n - \operatorname{rank} A(\mathfrak{p}).$$

For $1 \le r \le n$, the inequality dim $\ge r$ is detected by minors of size $n - r + 1$. If $r > n$, the fiber locus is empty and $\mathrm{Fitt}_{r-1}(M) = R$. The final ordinary proof explicitly separates this boundary. The formal block already includes upper-index normalization and empty/zero-minor checks. Fitting strata count minimal fiber generators, not automorphic multiplicities.

9 Derived support uses actual perfect models

`PaperXII.PerfectDerivedSupport` does not encode a complex by a bare list of supports. Its `PerfectComplex` contains an actual Mathlib object of the derived category, a bounded finite-projective cochain model, and an actual derived isomorphism from that model. Base change is computed degree by degree on the

projective model. The code proves compatibility with actual derived isomorphisms, so support does not depend on the chosen model.

A nonzero field fiber yields some nonzero actual derived cohomology object in an integer degree. The bounded projective model proves vanishing outside its bounds. The induced Hecke action comes from multiplication on the original cochain model, through scalar extension and passage to derived cohomology, and equals the specialized scalar character.

These are formal algebraic conclusions. They neither choose a classical weight nor establish classicality. Revised Claim 9.6 requires the classicality range to contain the model interval. Revised 12.4 permits applicability at the selected eigensystem itself. The original unrestricted versions remain partial in their original ledger. The cited external cohomological description of derived support is not needed by this production residue-field support proof.

10 Artin packets, residual augmentation and finite adequacy

Hecke packet construction starts with a supplied canonical ring decomposition into actual localizations. The input is `ArtinData.DecompositionR`, an R-algebra equivalence whose coordinates are proved to be the canonical localization maps. It supplies no module direct-sum decomposition and no module localization equivalence. Those are constructed subsequently.

```

From this input, Lean constructs orthogonal idempotents, their packet submodules, the direct sum, and the equivalence between the packet and the localized module. It verifies the map $v \mapsto v/1$. The selected local factor's nilpotent maximal ideal and an invertible generator on every other factor identify the packet with the simultaneous generalized eigenspace for one positive exponent. This does not assume semisimplicity. In characteristic zero, the projector trace is the dimension of its image cast into the field, and nonzero trace detects occupancy. Trace cancellation in positive characteristic remains a real boundary.

Auxiliary group-algebra transfer is constructed on the actual group basis and commutes with actual augmentation. Coinvariant recovery proves a quotient by all balancing relations and identifies it with the ordinary tensor product when the appropriate algebra is commutative. The right-module treatment handles arbitrary groups, including nonabelian two-groups. A supplied free basis descends to a coefficient basis with the same index set, including rank zero.

For a product of cyclic p-groups in characteristic p, the full multivariable truncated-polynomial algebra equivalence is constructed and its augmentation generators identified. The result excluding nontrivial idempotents covers every finite p-group, including nonabelian ones, by an orbit-span/fixed-vector argument over the prime field. The dyadic code proves that rational sign projectors are not integral and constructs $\mathbb{F}_2[C_2] \cong \mathbb{F}_2[X]/(X^2)$. None of this supplies dyadic arithmetic image, local geometry or classicality hypotheses.

The S_3 example over $\mathbb{F}_7$ is a Lean certificate for one finite representation. The modules construct the standard representation from the permutation module, prove absolute irreducibility, identify its trace-zero adjoint with sign plus standard, and connect averaging to actual first group cohomology. Canonical generalized-eigenspace projectors detect every nonzero adjoint constituent. Independent finite computations can check the printed matrices and trace pairings. Their scope remains separate from the formal certificate and from arithmetic adequacy applications. The adequacy convention remains a cited input.

11 Occupancy, stable cores and adic completion of classes

In one finite-dimensional carrier, nested idempotent ranges stabilize. In that carrier, nonzero ranges at every level yield a nonzero intersection. In changing carriers, the inverse limit is controlled by the actual intersections of transition images, not merely by nonzero individual levels. `PaperXII.StableCores` uses a `LinearSystem` with actual linear maps and identity/composition laws. It proves that transition images are antitone, that finite-dimensionality makes each stable core an eventual image, and that the core transition is surjective. Recursive lifting then produces a compatible nonzero vector above a chosen nonzero core coordinate.

Finite companion forests give branches when every finite level is nonempty. An empty level obstructs complete realizations whose actual finite reductions belong to those declared levels. It does not rule out representations excluded by an arbitrary admissibility restriction. The production `empty_level_no_realization` explicitly takes reduction maps from the supplied realization type into every forest level. Forests do not alone produce continuous integral representations with every arithmetic condition. Revised Claim 10.5 makes the missing effectivity inputs explicit: complete separated coefficient rings for finitely generated ideals, finite residue rings, finite occupied classes of actual continuous quotient representations, reduction compatibility, continuous coefficient maps, integral Frobenius polynomials with matching scalar changes, and declared polynomial ideal conditions valid in every admissible frame.

Finite frames turn finite admissible conjugacy classes into finite sets of actual representatives. Compactness selects strictly compatible representatives without assuming transition surjectivity or lifting a prescribed conjugating matrix. Entrywise reconstruction, including inverse entries, constructs the actual inverse limit of matrix groups. Continuity is derived from finite quotient continuity and the adic topology. Separatedness upgrades compatible polynomial and subgroup-triviality congruences to exact integral equalities. Evaluation then kills each declared polynomial ideal and factors through its actual quotient.

```

The conclusion retains a residual conjugacy class, not a prescribed residual matrix frame. Uniqueness up to integral conjugacy is not asserted. No arbitrary Hodge or Weil–Deligne condition is identified with a polynomial ideal without additional arithmetic work. Integral Frobenius lifts and occupancy at every precision are hypotheses, not outcomes of abstract compactness. A missing coefficient-place member is not supplied by propagation inside an existing compatible family.

12 Conditional realization and the five separate gates

The formal realization theorem compares actual matrix representations via an invertible linear intertwiner. It assumes a Hausdorff characteristic-zero topological field with continuous ring operations, continuous compared representations, a supplied semisimplification preserving characteristic polynomials, arithmetic density of the declared Frobenius conjugacy saturation, and a general algebraic Brauer–Nesbitt identification theorem over that coefficient field.

`PaperXII.DenseFrobenius` proves continuity of characteristic-polynomial coefficients and extends equality from the dense Frobenius conjugacy set to all group elements. The supplied Brauer–Nesbitt input then identifies the semisimple representations. Neither density nor the general Brauer–Nesbitt theorem is a newly introduced global Lean axiom: each is an explicit ordinary theorem argument, and the production result is conditional on it.

For a supplied universal representation, `specialize` is literally coefficient change into the chosen field. Its continuity is explicit. The two representations must have the same specialized Hecke polynomials on the same dense good set. The ordinary completion theorem has the universal specialization polynomial identity as a separate explicit premise. Its classicality input supplies the attached representation's matching polynomial identity. The final traditional definition 12.1 spells out these inputs. A nonzero fiber and an attached representation alone would not identify the universal specialization.

The five-gate modules derive finite-level support from the actual patched quotient/control data. A general comparison can use an actual inclusion of support subsets under a ring map, with ordinary or derived support as appropriate. The compatible Hecke point y satisfying $y \circ f = x$ is separately supplied. Support preservation alone does not provide such a point over the prescribed coefficient field: $\mathbb{Q} \to \mathbb{Q}(i)$ preserves full support but admits no extension of the identity point to $\mathbb{Q}$.

The chosen nonzero tensor vector or cohomology vector carries all prescribed Hecke eigenvalues. Classicality is applied to this actual eigensystem, and supplies an occurring automorphic object plus its attached representation. The representation comparison follows under the common-polynomial, continuity, density and semisimplification hypotheses. Propagation uses two already existing compatible families, the family attached to the same automorphic object, distinguished member identities, and their common algebraic spine.

Gate	Input and formal consequence
Residual	Arithmetic residual occupancy and representability supply the deformation problem, its ring and universal representation.
Patching	An applicable arithmetic theorem supplies patched carriers, control maps and full patched support. Lean descends support to the actual finite-level carrier.
Comparison	A support-preserving comparison and compatible Hecke point are supplied. Lean transports support and constructs a nonzero specialized eigenvector.
Fiber	Ordinary tensor or derived cohomology is constructed. The actual Hecke action becomes the specialized scalar character.
Realization	Applicability of classicality to the selected eigensystem, occurrence, attachment, common polynomials, density, semisimplification and Brauer–Nesbitt are supplied. Lean deduces the intertwiner.

13 External arithmetic inputs and editorial boundaries

The formal code begins after the relevant arithmetic objects have been supplied. Retained external inputs include representability and local quotient existence; universal arithmetic deformation representations; residual automorphic occupancy; applicability of a named patching package; classicality at the selected eigensystem; an occurring automorphic object and continuous semisimple attached representation; matching Frobenius normalizations; already existing attached compatible families; arithmetic Frobenius density; construction of semisimplification; and general original-field Brauer–Nesbitt. The canonical Artin localization decomposition and the adequacy convention are also supplied inputs.

An application must state a finite ramification set and coherent choices of Frobenius convention and polynomial normalization. The literal abstract Lean group is Γ. Its arithmetic realization as $G_{F,S}$, and density of the corresponding permitted conjugacy classes, are provided by the application. Chebotarev for finite quotients followed by continuity is the relevant density mechanism for an arbitrary declared

Hausdorff coefficient topology. Claims of historical novelty or citation support are not certified by the kernel.

The final traditional manuscript clarifies the statement context without changing production Lean: Claim 3.3 exposes the local structural map and the complete Hausdorff local coefficient-algebra point category; the proof of 6.4 treats $r > n$ explicitly; and Definition 12.1 exposes the same Frobenius polynomials and all realization hypotheses needed by 9.4. Compatible carrier actions and the scope of companion obstruction at the declared levels are also explicit, as are the finite ramification set and Frobenius convention. These are final editorial clarifications, tracked separately from the eight inherited amendments. They are not fresh kernel certification of a newly edited proposition.

The strongest global conclusion is conditional automorphic realization inside an explicitly declared supported and realized class, followed by propagation inside already existing compatible systems. Universal residual companions, existence of arbitrary compatible families, unrestricted reciprocity and an arithmetic theorem at coefficient prime two are not conclusions of these sources.

A Full source catalog

The complete 96-module production catalog follows in registered dependency order. “Thm.” counts each module’s public theorem declarations, including reused declarations where present. SHA prefixes aid visual comparison. The exact 64-character hashes and imports are supplied in `data/source_catalog.json` and `data/source_catalog.csv`. Source paths are determined by replacing dots in the module name with slashes and adding `.lean`, relative to `formal_release/lean/`.

B All 49 revised internal claims

The crosswalk lists every revised internal claim, its manuscript label, amendment status, original status and number of mapped targets. Every target name and source module is supplied in `data/claim_crosswalk.json`. The condensed module crosswalk is `data/claim_crosswalk.csv`. “Amended” means complete for the revised statement while the original statement retains its own status. Ordinary editorial clarifications described in Section 13 are separately tracked.

C A practical reading and inspection sequence

A reader examining a mathematical claim should first locate its revised number in the crosswalk, then read the exact production declarations, their ambient variables and the relevant proof. Follow internal imports to any structure or construction the theorem consumes. Determine which fields are supplied data and which declarations construct the desired maps, objects or identities. Match the point category, coefficient maps, topologies, completeness, finite-generation and locality assumptions with the intended application. Consult the original ledger when comparing against earlier wording.

For Claims 3.1 and 3.3, the central source chain is the raw tensor quotient, completion/closed quotient comparison, adic quotient topology, completed finite tensor, algebraic adic comparison/locality, global tensor transport, local condition factorization, Noetherian/local capstone and coefficient/local point category. Checking only ordinary tensor quotients or an assumed interface for the universal property would miss the constructed completed objects and their actual topologies.

For the arithmetic conclusion, trace the nonzero fiber or cohomology vector through the actual carrier and point. Verify classicality for that selected eigensystem, then check attachment, matching Frobenius polynomials, density, semisimplification and representation comparison over the original field. Finally ensure any propagated family already exists and belongs to the same attached automorphic object. This sequence explains exactly what the formalization establishes and what an arithmetic application must still provide.

Glossary

Definitions and reading references for the recurring language of the twelve chapters. Local meanings and hypotheses remain those of the cited mathematical treatment.

A

Automorphic Hecke datum

A Hecke algebra with a finite automorphic module or perfect complex, declared unramified Hecke polynomials, and a characteristic zero locus where classicality and an attached Galois representation are supplied. These realization inputs are part of the datum.

Chapter XII, Definition 9.1

See also: Hecke packet, Residual automorphic occupancy

B

Block diagonal plus low rank operator

An operator represented as a block diagonal part plus one thin factor times the adjoint of another. This separates independent packet work from a coupling term of rank at most the factor width. The abbreviation is BDLR.

Chapter VIII, Definition 3.3

See also: Packet operator representation, Output contract

Bridge datum

In the restricted Galois to type comparison, a supplied symplectic identification of two envelopes, compatible stabilizer action, and a common central character. At the prime two, compatible quadratic refinements and a lift to the central extensions are also required.

Chapter XI, Definition 11.1

See also: Symplectic envelope, Quadratic refinement

C

Clifford cocycle class

The cohomology class of the scalar factors by which multiplication of projective multiplicity operators differs from the group law. In the one break setting, its commutator pairing determines the associated symplectic envelope.

Chapter XI, Definition 9.3

See also: Symplectic envelope, Bridge datum

Common arithmetic spine

Algebraic Frobenius characteristic polynomials, coefficient-prime independent weight and determinant data, and prescribed ramified local labels that companion objects must share. Specifying the spine imposes compatibility conditions. It does not ensure that the corresponding residual fibers are occupied.

Chapter X, Definition 8.1

See also: Residual root, Residual forest, Automorphic Hecke datum

Compatibility

Agreement of specified constructions along two routes. For fine and coarse nonlinear models, applying the fine map and then coarsening must equal coarsening first and applying the coarse map. Arithmetic compatibility uses the separately declared common data.

Chapter III, Definition 20.1

See also: Refinement defect, Common arithmetic spine

Complete multiplicative filtration

A decreasing filtration by two-sided ideals whose products add filtration depths, whose intersection is zero, and whose compatible quotient system recovers the algebra. Positive transfer weights then control convergent expansions in the filtration topology.

Chapter II, Definition 5.1

See also: Weighted transfer series, Lift tree

Complete packet pruning

A set of nodes in a finite refinement tree meeting every root-to-terminal path exactly once, with no selected node above another. Parent projectors split into child projectors, so the selected packets still sum to the identity.

Chapter V, Definition 11.1

See also: Refinement, Packet system

Conditional expectation projector

For a fixed finite probability space and partition, the operator replacing a function by its probability-weighted mean on each partition block. It is an orthogonal projector in the corresponding weighted Hilbert space. Nested partitions yield compatible projections.

Chapter VI, Section 6

See also: Projector, Packet system

Congruential Euler coefficients

Coefficients defined by the reciprocal of an exponential section with width N and address j. The original degree-indexed coefficients and normalized packet coefficients differ by the factor j!. Both the normalization and the distinction between degree and row matter in congruences.

Chapter IX, Definition 3.1

See also: Packet row, Hurwitz integral series, p-adic precision

Connection

A chosen family of invertible maps between chart coordinates. The minimal connection is normalized at each chart. The stronger reversible connection also inverts transport on reversed edges. Neither definition alone imposes the cocycle law or identifies the connection with canonical coordinate transport.

Chapter III, Definition 5.1

Chapter III, Definition 5.5

See also: Flatness of a connection, Gauge change, Holonomy

Cyclic vector

A single vector whose orbit under the declared unital algebra generates the whole module by finite linear combinations. A nonzero module has seed rank one precisely when it has such a vector. Cyclicity is always relative to the acting algebra.

Chapter I, Proposition 4.2

See also: Seed, Seed rank, Generated hull

D

Derived support

For a perfect complex over a commutative ring, the prime ideals at which the derived tensor product with the residue field is nonzero. This support detects the complex after specialization, rather than relying on one selected cohomology module.

Chapter XII, Definition 6.14

See also: Module support, Ordinary patching datum

E

Exact lumpability

Compatibility between a fine Markov transition and a coarse transition under a declared aggregation map. The one-step intertwining identity makes fine evolution followed by aggregation agree with coarse evolution at every nonnegative integer time.

Chapter VI, Theorem 5.1

See also: Compatibility, Refinement defect, Transfer semigroup

F

Feshbach reduction

Elimination of hidden packets through their resolvent, producing an effective operator on the retained space. The correction records excursions through hidden packets. The exact resolvent identity requires the stated inverses and generally differs from bare compression.

Chapter VII, Theorem I.9.1

See also: Transfer block, Memory kernel

Flatness of a connection

The cocycle condition: transport through any intermediate chart equals the declared direct transport. In the reversible pair setting, flatness is equivalent to trivial triangle holonomy. Flatness alone does not say that the connection is already canonically calibrated.

Chapter III, Definition 5.6

See also: Connection, Holonomy, Gauge change

Forward difference

The difference between a sequence value after a declared step and its original value. Iterating this operation gives higher differences. In the Euler packet results the step acts on packet rows, so ordinary-degree displacement must be converted using the packet width.

Chapter IX, Definition 3.4

See also: Packet row, Congruential Euler coefficients, p-adic precision

G

Gauge change

A change of coordinate representative at each chart by an automorphism. It acts on a connection by conjugating the source and target representatives separately. Cocycle defects transform covariantly, while loop holonomy is conjugated at its base.

Chapter III, Definition 6.1

See also: Connection, Flatness of a connection, Holonomy

Generated hull

All finite sums of seed vectors acted on by elements of the declared algebra. In a topological realization, the topological hull is its closure. Algebraic generation and dense generation are distinct because closure may add limits with no finite addressed expression.

Chapter I, Definition 2.7

See also: Seed, Seed rank, Realization

Global deformation datum

A residual representation, local deformation rings and represented local-condition quotients, a global deformation ring, and compatible maps imposing those local conditions globally. Existence and representability of these objects require their own hypotheses. The datum does not establish automorphic occupancy.

Chapter XII, Definition 2.1

See also: Residual root, Residual automorphic occupancy, Ordinary patching datum

H

Hecke packet

The part of a finite Hecke module selected by a central idempotent of its finite-dimensional commutative Hecke algebra. It is nonzero precisely at an occupied maximal ideal. Over an algebraically closed field it is a simultaneous generalized eigenspace, retaining nilpotent data.

Chapter XII, Theorem 8.2

See also: Module support, Automorphic Hecke datum, Stable core

Holonomy

The composite transport around a loop for a chosen connection, based at its starting chart. Triangle holonomy measures the failure of a reversible pair connection to satisfy its cocycle law. It is not an invariant of an unspecified change of coordinates.

Chapter III, Definition 5.9

See also: Connection, Flatness of a connection, Gauge change

Hurwitz integral series

An exponential generating series whose factorial-basis coefficients are p-adic integers. Products and differentiation preserve this lattice. A series in it with unit constant coefficient has its reciprocal in the same lattice, supporting the reciprocal-transfer congruence arguments.

Chapter IX, Definition 4.1

See also: Congruential Euler coefficients, p-adic precision

K

Kraus channel

A finite sum of maps sending a matrix to K times that matrix times the adjoint of K, with the adjoint products summing to the identity. This normalization makes the resulting completely positive map trace preserving.

Chapter VII, Classical Input I.7.2

See also: Quantum seed system, Packet system

Krylov space

The span of a vector and its successive images under one operator, through a specified finite order. This records how repeated application enlarges the generated space. Packet decompositions interact with it under the invariance hypotheses stated in the relevant result.

Chapter VIII, Definition 7.1

See also: Cyclic vector, Generated hull, Packet operator representation

L

Lift tree

A rooted tree of approximation classes at increasing filtration depths. A child reduces to its parent and satisfies the next depth condition. Nonempty levels and finite branching provide a compatible branch. Completeness, separatedness and continuity are further needed to recover an exact solution.

Chapter III, Definition 23.5 and Theorem 23.6

See also: Complete multiplicative filtration, Obstruction class, Residual forest

M

Memory kernel

The time-dependent operator describing how eliminated packets return influence to retained packets. In the finite linear system it is a transfer into the hidden block, hidden evolution, and transfer back. Its Laplace transform is the corresponding self-energy under the stated spectral condition.

Chapter VI, Section 13.1 and Theorem 13.2

See also: Feshbach reduction, Transfer semigroup, Transfer block

Module support

The prime ideals of a commutative ring at which localization of the module is nonzero. Full support means every prime is occupied in this algebraic sense. It does not by itself provide a classical automorphic realization.

Chapter XII, Definition 6.1

See also: Near faithfulness, Derived support, Hecke packet

Monodromy packet chain

A finite sequence of packet spaces joined by a nilpotent operator that moves each packet down one level. A compatible Frobenius operator scales this transfer by the declared residue-field factor. Its powers are sums of paths along the chain.

Chapter XI, Definition 2.2 and Proposition 2.3

See also: Transfer block, Transfer graph

N

Near faithfulness

For a finite module over a Noetherian ring, nilpotence of its annihilator ideal. This is equivalent to full module support. If the ring is reduced it is also equivalent to faithfulness. The finiteness and ring hypotheses are part of the equivalence.

Chapter XII, Theorem 6.7

See also: Module support, Ordinary patching datum

O

Obstruction class

The class of a defect in the cokernel of a declared linear correction map. It vanishes exactly when that linear correction can remove the defect. The quotient, not the size of the defect, determines this solvability question.

Chapter III, Definition 21.1 and Theorem 21.2

See also: Refinement defect, Obstruction packet, Lift tree

Obstruction packet

A named packet with a certificate that the residual of one specified candidate is nonzero. It rules out that candidate under the declared solution condition. It neither constructs a solution nor proves that every possible candidate is obstructed.

Chapter III, Definition 7.1 and Theorem 7.2

See also: Obstruction class, Residual, Packet

Ordinary patching datum

A Noetherian patched ring, an ideal, and a finite patched module, together with identifications of the finite-level ring and module as their quotients. Full patched support descends under these hypotheses. Automorphy requires additional arithmetic data.

Chapter XII, Definition 6.10

See also: Module support, Near faithfulness, Global deformation datum

Output contract

The mathematical object an algorithm is required to return, such as an explicit vector, matrix, factors, or an implicit operator with an application rule. Costs are comparable only after the represented object and required output are fixed.

Chapter VIII, Definition 2.7

See also: Packet operator representation, Block diagonal plus low rank operator

P

p-adic precision

A lower bound on the p-adic valuation in the declared integral coefficient ring. The Euler congruence statements assign infinite valuation to zero. Divisibility in the field alone does not express precision, and special finite conventions for a zero step are stated separately.

Chapter IX, Definition 3.4

See also: Congruential Euler coefficients, Forward difference, Hurwitz integral series

Packet

In the linear theory, a component selected by a declared projector, usually identified with its range and index. Analytic, signal and arithmetic realizations attach their own additional structure. The meaning of a packet is therefore read with its specified system.

Chapter I, Definition 7.1

See also: Packet system, Projector, Transfer block

Packet analysis and synthesis

Analysis sends an object to its tuple of projected packet components. Synthesis adds those components in the ambient space. For a finite complete packet system the maps are inverse isomorphisms. Infinite versions require a specified convergence mode and corresponding bounds.

Chapter I, Definition 7.4 and Theorem 7.5

See also: Packet system, Packet support, Refinement

Packet jet

A higher derivative restricted to specified input packet spaces and projected to a specified output packet. Summing over all addresses reconstructs the derivative exactly. The analytic statements require the stated bounded projectors and continuous Fréchet differentiability.

Chapter III, Definition 17.1

See also: Packet, Transfer block

Packet operator representation

A finite packet layout, a declared set of active input-output addresses, and a linear block at each address. Evaluation extends each local block to the ambient direct sum and adds the blocks. Thus the representation has an explicit operator meaning.

Chapter VIII, Definition 2.2

See also: Transfer block, Output contract, Block diagonal plus low rank operator

Packet row

The index n within a fixed coefficient packet of width N. For the reciprocal Euler family, row n corresponds to ordinary degree Nn. A step of u rows therefore changes ordinary degree by Nu, a distinction needed when stating periods and difference estimates.

Chapter IX, Section 4, equations (4.1)-(4.2)

See also: Congruential Euler coefficients, Forward difference

Packet support

The set of packet indices on which an object has a nonzero projected component. A packet-pure vector has at most one such index, including the zero vector. This is different from module support in a prime spectrum.

Chapter I, Definition 7.2

See also: Packet, Seed rank, Module support

Packet system

A finite family of idempotent operators that annihilate one another and sum to the identity, giving an exact direct-sum decomposition into their ranges. Orthogonality is an additional condition when stated. Some chapters remove zero packet spaces by convention.

Chapter I, Definition 7.1

See also: Projector, Packet analysis and synthesis, Refinement

Perfect reconstruction

Recovery of every input by composing a filter bank with its synthesis bank, with any permitted gain and delay declared explicitly. The criterion is an identity of Laurent-polynomial matrices. A delay in decimated channel indices differs from a delay in original sample addresses.

Chapter V, Theorem 4.1

See also: Polyphase channel, Packet analysis and synthesis

Polyphase channel

The decimated sequence obtained by retaining one residue class of sample addresses and reindexing it on a coarse lattice. Its masked counterpart remains on the original lattice with other samples set to zero. Interleaving reconstructs the original sequence from all channels.

Chapter V, Section 2 and Theorem 2.1

See also: Residue selector, Perfect reconstruction

Projector

An idempotent linear operator: applying it twice has the same effect as applying it once. Its range is the selected component. The general packet calculus does not require an orthogonal projector, although Hilbert space and quantum results may impose self-adjointness.

Chapter I, Definition 7.1

See also: Packet system, Packet

Q

Quadratic refinement

Over the field with two elements, a quadratic function whose polar difference recovers a specified symplectic form. The alternating form alone does not determine the refinement. This additional datum controls dyadic phase information in the arithmetic packet constructions.

Chapter XI, Definition 13.1

See also: Symplectic envelope, Bridge datum

Quantum seed system

A finite Hilbert space with a nonzero seed, a declared operator grammar, constraints, packet systems at refinement levels, and the relevant dynamical and topological data. Its generated span is algebraic. Reachability by a restricted physical gate set is a separate question.

Chapter VII, Definition I.1.1

See also: Seed, Cyclic vector, Kraus channel

R

Realization

An assignment of spaces and linear maps to a typed operator grammar that satisfies its relations. More generally, a domain realization interprets specified abstract seed constructions in a chosen mathematical setting. Which operations and universal properties survive must be declared.

Chapter I, Definition 2.1

See also: Typed operator grammar, Realization functor, Seed

Realization functor

A functor from abstract seed systems to a declared domain category, equipped with a preservation profile. The profile states which identities or universal properties it preserves, such as sums, compositions, packet idempotents, quotients, or completions.

Chapter I, Definition 11.1

See also: Realization, Typed operator grammar

Reduced denominator

The one-variable entire function obtained from the signed exponential denominator by using a coordinate w equal to the Nth power of z. A root in the reduced coordinate records a root-of-unity orbit in the original variable, with multiplicities retained.

Chapter IV, Definition 5.7

See also: Residue selector, Transfer tangent, Zero power sum

Refinement

A finer packet system whose projectors sum to each coarse projector according to a surjective parent map. Fine packet ranges lie in their parent ranges. Exact refinement regroups complete component vectors and need not discard information.

Chapter II, Definition 3.2

See also: Packet system, Packet analysis and synthesis, Complete packet pruning

Refinement defect

The difference between applying a fine model and then coarsening, and coarsening first and applying the coarse model. Its vanishing expresses exact compatibility. A correction map must be specified before this vector defines a corresponding obstruction class.

Chapter III, Definition 20.1

See also: Compatibility, Obstruction class, Exact lumpability

Residual

In the candidate-certificate language, the value of a declared test at a candidate and packet. A solution makes every such value zero. This use of residual as a test value is distinct from reduction to a residue field in arithmetic deformation problems.

Chapter III, Section 7.1 and Definition 7.1

See also: Obstruction packet, Residual root

Residual automorphic occupancy

Existence of a nonzero localized automorphic or cohomological Hecke carrier realizing a specified residual representation and local conditions. It is an input at residual depth. Positive-depth deformations over another residual root do not supply it.

Chapter XII, Definition 2.4

See also: Residual root, Automorphic Hecke datum, Global deformation datum

Residual forest

The family of formal deformation problems above the admissible residual roots. Higher-depth objects are related by reduction, so each root has its own lifting branches. Declaring the forest does not establish that every intended branch or characteristic zero realization exists.

Chapter X, Definition 1.1

See also: Residual root, Lift tree, Common arithmetic spine

Residual root

An object over the residue field, fixed as the reduction of all objects in its residual fiber. Positive-depth corrections preserve this root. A universal arithmetic seed system therefore records all admissible roots rather than assuming one root represents every residual class.

Chapter X, Definition 1.1

See also: Residual forest, Residual automorphic occupancy, Visibility weight

Residue selector

The coefficient projector retaining exactly the exponents in one congruence class modulo a positive integer. It is defined directly by a coefficient mask and needs no division. A realization as a roots-of-unity average requires additional orthogonality hypotheses.

Chapter II, Definition 4.1

See also: Roots of unity filter, Polyphase channel, Refinement

Roots of unity filter

A finite character average realizing a residue selector when the required Fourier orthogonality certificate holds. Over a field with a primitive root, the usual normalization divides by the width. Over more general coefficient rings, the coefficient selector remains meaningful even when that average is unavailable.

Chapter II, Theorem 4.3

See also: Residue selector, Separation weight

S

Seed

A distinguished starting element acted on by a declared operator algebra or grammar. A seed family generates its hull through addressed operator expressions and finite sums, with closure added only in a specified topological regime. The acting algebra is fixed independently of the target.

Chapter I, Definition 2.6

See also: Generated hull, Seed rank, Typed operator grammar

Seed rank

The least size of a family generating a module under the declared acting algebra. In the topological version, generation is replaced by dense generation. The zero module has rank zero. Changing the acting algebra can change the seed rank of the same underlying space.

Chapter I, Definition 4.1

See also: Seed, Generated hull, Cyclic vector

Seed zeta function

The formal power series whose coefficient at each positive depth counts the finite objects above one residual root at that depth. Smooth and weighted charts yield explicit formulas under their stated assumptions. It records branching counts, not just the existence of a lift.

Chapter X, Definition 6.1

See also: Residual forest, Visibility weight

Separation weight

The least exponent of a uniformizer that makes a rational projector preserve a specified integral lattice, provided such an exponent exists. It records the precision needed to clear that projector on that lattice and is distinct from the visibility depth of two coordinates.

Chapter II, Definition 7.6

See also: Projector, Visibility weight, Roots of unity filter

Singular packet

In the signal chapter, a step or truncated-power component recording a value jump or a derivative jump at a declared breakpoint. Removing the trace jumps leaves the regular remainder covered by the stated Sobolev assumptions. Representation alone does not solve data-driven recovery.

Chapter V, Section E7

See also: Packet, Perfect reconstruction

Stable core

At one level of an inverse system of finite-dimensional spaces, the intersection of the images of every later level. It retains vectors that remain liftable arbitrarily far. Nonzero stable cores at every level provide compatible nonzero inverse-limit vectors, unlike mere nonvanishing of unrelated levels.

Chapter XII, Definition 8.9 and Theorem 8.11

See also: Hecke packet, Lift tree

Symplectic envelope

For a one break Clifford datum, the quotient of the finite elementary abelian group by the radical of its intrinsic commutator pairing. This removes the degenerate directions of that pairing. Comparison with a type-side envelope requires the additional bridge data.

Chapter XI, Definition 9.5

See also: Clifford cocycle class, Bridge datum, Quadratic refinement

T

Transfer block

The part of an operator carrying one input packet to one output packet: first select the input, apply the operator, and select the output. Summing all blocks reconstructs the operator for a finite complete packet system.

Chapter I, Definition 8.1

See also: Packet system, Transfer graph, Packet operator representation

Transfer graph

A directed graph on packet indices, with an edge where a declared algebra generator has a nonzero transfer block. Reachability limits where generated operators may have nonzero blocks. An allowed path does not prevent cancellation or guarantee a nonzero transfer.

Chapter I, Definition 9.1

See also: Transfer block, Seed rank, Packet operator representation

Transfer semigroup

A family of evolution operators whose composition adds time and whose value at zero is the identity. In the finite setting it is generated by a matrix exponential. The sign convention differs between generators of evolution and nonnegative diffusion operators.

Chapter VI, Definition 1.1 and Theorem 1.2

See also: Memory kernel, Exact lumpability

Transfer tangent

The negative logarithmic derivative of the signed exponential denominator in the cyclic analytic family. It is also the logarithmic derivative of the first reciprocal power. Its expansion connects reciprocal coefficient recurrences to logarithmic coefficients and reduced zero power sums.

Chapter IV, Definition 8.1

See also: Reduced denominator, Zero power sum

Typed operator grammar

A quiver of permitted source and target types together with linear relations among paths having the same endpoints. Its quotient path algebra encodes composition and relations. A realization assigns spaces to vertices and maps to arrows satisfying those relations.

Chapter I, Definition 2.1

See also: Realization, Seed, Transfer graph

V

Visibility weight

The first precision depth at which two distinct integral packet coordinates have different reductions, when such a depth exists. At the prime two, signs may share a residual reduction yet separate at a later depth. This weight measures separation of coordinates, not a projector denominator.

Chapter X, Definition 5.1

See also: Separation weight, Residual root, Seed zeta function

W

Weighted transfer series

A generating series for walks in a finite directed multigraph with positive integer edge weights and scalar multiplicities. It sums multiplicity products and endpoint weights at each total weight, including the empty walk. The positive weights make each coefficient well defined.

Chapter II, Definition 6.1

See also: Transfer graph, Complete multiplicative filtration

Z

Zero power sum

A sum of inverse powers of the reduced zeros of the cyclic analytic denominator, counted with multiplicity. For section order N at least two, these sums converge absolutely and agree with the normalized logarithmic coefficients through the genus-zero product.

Chapter IV, Definition 12.5 and Theorem 12.6

See also: Reduced denominator, Transfer tangent

[3] *Original Contract162*. Retained source in Closure Attempt162, also preserved among Block 167 dependencies.

[4] *Continuation 110: Arithmetic Bridge*. Retained continuation and its handoff, source contracts and evidence.

[5] *Continuation 111: Canonical Attachment*. Retained README, source contract and conditional proof audit.

[6] *Continuation112: Realization Test*. Retained complex-cochain and whole-carrier obstruction records.

[7] *Continuation113: Arithmetic Descent*. Retained cubic occurrence and corrected-character test records.

[8] *Finite Extension Test*. Extension Diagnosis163. Orthogonal central products, scalar extensions and coprime actions.

[9] *Compact Binder Theorem*. Closure Attempt162, compact branch. Fixed templates, joint finite solvability and exact limits.

[10] *Two Input Witness164*. Status, wild and unramified pair records, and twist-transport notes. Conditional source dependencies retained.

[11] Proof166. Direct trace-zero realization in arbitrary odd-prime length. Ordinary proof synthesis.

[12] *Trace Zero Artin–Schreier Tower166* and *Recursive Tower166*. Parameter, corestriction and defining-sequence arguments.

[13] *Trace Zero Character Induction166*. Full native characters, transfer, correction and shallow-unit extension.

[14] *Leading Layer Capacity166*. Host subspace and scalar-pushout attachment. Its separate classical induction application is not an input to the direct constructor.

[15] Proof167. Weighted dyadic realization and low-rank enlargement.

[16] *Dyadic Artin–Schreier Tower167*. Recursive matrices, native trace one and defining levels.

[17] *Dyadic Full Character167*. Depth-weighted compatibility and full-character extension.

[18] *Dyadic Capacity167*. Graded quotient counts, low-rank obstruction and skipped-degree profile comparison.

[19] *Dyadic Markings167*. Whole finite extensions, transported lifts and independent native quadratic refinements.

[20] *Enlarged Carrier Contract167*. Actual compact carriers, quotient recovery and central-normalized finite projectors.

[21] *Rank2 Enlarged Carrier167*. Actual rank-two compact group and Heisenberg enlargement.

[22] *Rank4 Enlarged Carrier167* and *Rank4 Induction by Stages167*. Actual rank-four carrier, normalization and same-candidate induction.

[23] *Stabilizer Contract166*. Original source hypotheses and the stronger native inner-normalizer obstruction.

[24] *Scalar Native Attachment166*. Genuine whole-carrier inertia phases and finite-cover descent.

[25] Colin J. Bushnell and Philip C. Kutzko. *The Admissible Dual of GL(N) via Compact Open Subgroups*. Annals of Mathematics Studies 129. Princeton University Press, 1993. Exact theorem and page locators are given in Section 13.

Arithmetic realization studies: monomial routes and Clifford descent

Source register

The machine-readable source map gives package-relative paths, SHA-256 hashes and selected locators. The short labels below identify the sources cited in the text. A source title containing “completion” does not override its actual hypotheses or verification status.

M *PSC Langlands Monomial Completion*, recovered manuscript and *Completion Ledger*. In particular: local monomial completion, prime-cyclic subgroup chains, and global monomial induction. Classical rank-one and automorphic-induction inputs remain explicit.

M45 Actual Monomial Local Global. Lean source, source-lineage and claim-classification notes, a preliminary preservation record and two incomplete build logs. The terminal successful receipt was not recovered.

C112 *Continuation112 Realization Test*. The genuine characteristic-five Clifford fixture, symmetric characteristic-three fixture, and source-realizability report. Their arithmetic spectrum restrictions are retained with their original scope.

C113 *Arithmetic Construction and Exact Occurrence Boundary113*. Characteristic-zero source, independent simple character, cyclic automorphic induction, tame descent and central normalization. Rational cyclotomic programs retained.

C113-S
Self Twist Audit113, *Failures113*, and the independent all-extension obstruction check. Original-character exclusion, the changed full-character correction, and the unresolved corrected-character occurrence.

C161 *Clifford Size and Inputs161*. Genuine normal-chain dimensions and the conditional host-capacity comparison. Abstract packet lists are not substituted for actual source multiplicities.

B162 *Compact Binder Theorem*, Closure Attempt162. Fixed compact models, simultaneous congruences and exact limits.

Corner
Structural Corner Note, explicit binder extension, with the full sixteen-coordinate symbolic calculation. Fifth-coordinate repair and surviving leading-coefficient obstruction.

B165 *General Cubic Binder165*. Square-zero support, whole-cycle corestriction and the arbitrary-exponent degree-nine construction, under its arithmetic refinement hypotheses.

BH99 Colin J. Bushnell and Guy Henniart. *Local tame lifting for* $\mathrm{GL}(N)$. *II: Wildly ramified supercuspidals*. Astérisque 254, 1999. Selected statements: Theorem 1.3, Theorem 1.8, Proposition 2.2, §2.3, and §5.4. Printed page references and the source-access record are in the audit file.

Imai Koto Imai. *Ramification groups of some finite Galois extensions of maximal nilpotency class over local fields of positive characteristic*. Manuscripta Mathematica 176, article 66 (2025), DOI 10.1007/s00229-025-01664-5. Example 3.8(1) and its stated ramification hypotheses. The source audit records the exact publication metadata returned by the primary source.

Arithmetic realization studies: conductors and native markings

30.4 Source register

The package's machine-readable source map supplies paths and hashes for inherited records. Page numbers below are printed pages unless a PDF-page locator is explicitly stated. Web-viewed primary sources are recorded as viewed sources, not as locally downloaded byte-pinned copies.

[Q13] *Adjoint Conductor Test161*. Retained dependency of Block166. The source invariant and conditional period-nine actual-order certificate. SHA-256 and exact source path are in the source map.

[Q14] *Principal Order Conductor161*. Principal grades, leading-level normalization and necessary source matching.

[Q15] *Arithmetic Constructor Audit*. The original source-defined induction and tame-descent branch, with full-character and source-input boundaries.

[Q16] *Dyadic Markings167*. Full central extensions, transported finite markings, fixed native refinements and the sharp capacity criterion.

[D167] *Dyadic Capacity167*. Full and skipped defining profiles, floor/ceiling grade counts, and the rank-eight shared-invariant example.

[BK] Colin J. Bushnell and Philip C. Kutzko. The Admissible Dual of GL(N) via Compact Open Subgroups. Annals of Mathematics Studies 129, Princeton University Press, 1993. Relevant inherited inputs: recursive character orders, minimal commutator control, refinement, 6.2.5 and compact-type formal degree. The earlier selected audit remains distinguished from the recorded conductor and marking source audit.

[BH99] Colin J. Bushnell and Guy Henniart. Local tame lifting for GL(n) II: wildly ramified supercuspidals. Astérisque 254, 1999. Selected audit: introduction p. 2, 1.3 p. 15, 1.7 p. 18, 2.3 pp. 23–25, 6.1 pp. 53–54. The PDF page index is the printed page plus four when counted from zero.

[AP] Anne-Marie Aubert and Roger Plymen. *Plancherel measure for GL(n,F) and GL(m,D): explicit formulas and Bernstein decomposition*. arXiv:math/0302169v4, 4 October 2004. Used: formulas (17), (29), Theorems 6.5 and 6.9, Remark 6.7 and the conductor convention in Section 4. The formal-degree pages inspected are pp. 19, 26–28.

[BH13] Colin J. Bushnell and Guy Henniart. *To an effective local Langlands correspondence*. arXiv:1103.5316v2, 9 October 2013. The characteristic note on p. 8 is the selected input. Its effective construction is not used to supply its own totally wild starting correspondence.

[HL11] Guy Henniart and Bertrand Lemaire. Changement de base et induction automorphe pour GL(n) en caractéristique non nulle. Mémoires de la Société Mathématique de France 124, 2011. DOI: 10.24033/msmf.436. The bibliographic record was checked. Detailed statements retain inherited audit status because the full PDF was unavailable during the recorded audit.
